NEW FM GAIN RINGO RANGER...you'll say "IT WORKS", when you try this exciting new antenna! Ringo Ranger is even better than the popular Ringo. Ranger has more gain for extended range. Easily mounted on a mast or existing tower, Ranger consists of a one eighth wave phasing stub and three half waves in phase to concentrate your signal at the horizon where it can do you the most good. Your present AR-2 can be extended with a simply installed RANGER KIT.

- **ARX-2** 100 watts 146-148 MHz $26.50
- **ARX-220** 100 watts 220-225 MHz $26.50
- **ARX-450** 100 watts 435-450 MHz $26.50
- **ARX-2K** Ranger Kit $10.95

NEW FM MOBILE... Fiberglass 5/8 wave professional mobile antenna for roof or trunk mount. Superior strength, power handling and performance.

- **AM-147T** 146-175 MHz mobile $29.50

NEW 4 POLE... economically priced for primary repeater or home QTH, this antenna has been proven in hundreds of repeater installations. It is a four dipole gain array for mast or tower mounting. It has sealed coax harness for direct 52 ohm feed. The antenna can be adjusted for a 180° or 360° radiation pattern. Another unmatched antenna value by Cush Craft.

- **AFM-4D** 1000 watts 146-148 MHz $52.50
- **AFM-24D** 1000 watts 220-225 MHz $48.50
- **AFM-44D** 1000 watts 435-450 MHz $46.50

ROCK CRUSHER

ALPHA 374

Once upon a time you needed a great big amplifier in order to have a big signal. Now a sleek ALPHA 374 does the job with much less fuss and greater convenience. Regardless of what other linear amplifier you're now using or considering, you'll do yourself a big favor by taking a close look at the ALPHA 374. For instance . . .

- The ALPHA 374 LOAFS ALONG AT MAXIMUM LEGAL POWER, continuous duty, all modes — 2+ KW PEP sideband (even with heavy clipping) or a full kilowatt of locked-key carrier.

- OPERATING CONVENIENCE SETS THE ALPHA 374 APART. You change bands at the flip of a switch — use the 'bandpass' mode and never touch a tuning or loading control if load VSWR is under 1.5:1 or so. If you think you can improve on the excellent bandpass performance by tuning up manually, give it a try — the controls are at your fingertips and the '374 is fully metered and protected.

- THE '374 IS REMARKABLY RUGGED AND RELIABLE. Tubes and transformers tend to be the components most likely to fail in high power amplifiers. In their first year of widespread amateur use, ALPHA 374s accumulated zero transformer failures and less than one-third of one percent Eimac 8874 ceramic triode tube failures — a nearly unbelievable first-year record for the no-tune-up ROCK CRUSHER!

- TAKING DELIVERY AND SETTING UP AN ALPHA 374 IS EASY, TOO. It can be shipped in two convenient cartons via fast, safe UPS; you never have to lift more than 36 pounds. Just place the Hipersil® transformer in the cabinet and plug it in; you're ready to go with true maximum legal power — in one cubic foot.

The ALPHA 374 IS GUARANTEED FOR A FULL YEAR AND COSTS JUST $1295. If you buy one, will you be happy with it? Yes . . . or we'll buy it back. (Offer limited; phone or write now for full details.)

The ALPHA 77D "ULTIMATE" LINEAR IS NOW BEING DELIVERED AT $2695. Some units are still available from second production run, which starts soon. Call for information. Six and two meter full kilowatt ALPHA V74 available shortly; $1195 introductory price.

Stand by for the latest word on Collins' 51S-1 receiver.

The word for Collins' 51S-1 is the same today as it's been for every one of its 12 years: outstanding.

Amateurs say it's an ideal addition to their stations as a primary or backup receiver. It's stable, sensitive and extremely accurate, assuring optimum reception of USB, LSB, AM, CW, and RTTY signals in the 2.0- to 30.0-MHz frequency range. With an accessory available that permits operation between 200 kHz and 2.0 MHz.

There's a choice of either 800-Hz or 300-Hz CW filters and of either 2.4- or 2.75-kHz mechanical filters for SSB. For AM, there's a standard 5-kHz bandwidth or optional 6-kHz mechanical filter.

Commercial communicators and shortwave listeners alike appreciate the 51S-1 for its quality reception of signals from anywhere in the world. International news broadcasts, amateur and military nets, air-to-ground monitoring and ships at sea.

The 51S-1 is available now, at a price that makes it very appealing for this class of receiver. See your Collins distributor, or contact Amateur Radio Marketing, Collins Radio Group, Rockwell International, Cedar Rapids, Iowa 52406. Telephone 319/395-4507.

As more and more amateurs are discovering, the commercial double-balanced mixer modules which are currently available are the clear choice when you are designing systems which require frequency conversion. The advantages of using these devices (along with sample circuits) were outlined in *Ham Radio* as long ago as 1968, and more recently in the other amateur radio magazines. Although the double-balanced mixer offers low distortion and high isolation, it suffers from fairly high conversion loss. While single-balanced mixers offer lower conversion loss and can be built less expensively, they do not provide the low distortion and high isolation characteristics of the double-balanced design.

Now, however, engineers at Hewlett-Packard have developed a single-balanced mixer with isolation, distortion and conversion-loss characteristics that equal or exceed those of some double-balanced mixers now on the market. Furthermore, the H-P printed-circuit balanced mixers, part number 5082-9200, are many times smaller (0.57" wide, 0.50" high).

With local-oscillator injection in the range from 200 to 900 MHz, conversion loss of the H-P balanced mixer is about 6.5 to 7.5 dB, a nearly 1 dB improvement over the performance of double-balanced circuits. In addition, isolation is 15 to 20 dB higher, being 45 dB at 200 MHz and 25 dB at 900 MHz. The maximum frequency is specified at 1200 MHz although selected devices would very likely provide good performance on the 1296-MHz amateur band.

In terms of distortion, at a local-oscillator level of +10 dBm (10 mW), the third-order intercept is typically +23 dBm and the 1 dB compression point occurs at +6 dBm. The second-order intercept is at +38 dBm, a roughly 10 dB improvement over conventional double-balanced mixers. Although a filter must be added at some later stage to separate the rf and i-f signals, this is not a particular disadvantage in communications circuits because a selective i-f filter is usually placed in the circuit immediately after the frequency-conversion stage.

Although balanced mixers are never quite as good in practice as they are in theory because of circuit imbalances, the various mismatches often cancel each other to a large degree. To achieve high performance in the new H-P mixer engineers further improved the matching, balancing and symmetry of the circuitry by removing the human element from the manufacturing process. The transformers, for example, are not wound by hand, but are etched on a printed-circuit board with spacing between windings controlled down to 0.001 inch (0.03mm). This technique also balances the parasitic capacitances between windings. With hand winding these elements vary widely as does the overall balance of the circuit.

Since diode matching is important in balancing a mixer, the H-P designers chose their own Schottky process because of its high yield of matched-diode pairs. With the carefully controlled printed-circuit transformers and closely matched diodes, the result is a 1% matching in forward voltages and a 0.1 pF capacitance match.

Although priced at $11 in small quantities, the cost of the H-P mixer drops to less than $2 each in production quantities, so it should see widespread use in commercial applications.

THE FIRST AND STILL
THE LEADER!
the exciting super
compact IC230

PUT OVER 67 CHANNELS IN THE PALMS OF YOUR HANDS

SPECIAL FEATURES:

- No More Crystals . . . Over 67 . . . fully synthesized channels available.
- All Channel Capability . . . Travel with confidence that you'll be able to work all repeaters along the way.
- Super Compact . . . 2.28" high x 6.14" wide x 9.72" deep at a weight of only 5.5 lbs.
- Quick Dismount Mobile Mount . . . Allows quick car installation.
- Easy Operation . . . Punch up frequency, select repeater or simplex mode, and you're on the air. (A crystal may be added for a unique repeater frequency.)
- Modular Construction . . . In case of a problem, modules can easily be removed and sent for repair. A replacement module will be air mailed to minimize down time.
- Super Hot Receiver . . . Better than .4uv / 20db. sensitivity, helical filters to eliminate intermod . . . plus a super E filter and a mosfet front end.

IF THERE IS A SIGNAL, YOU'LL HEAR IT ON THE IC-230!

THE GETTYSBURG LOG-JAM continues to plague both Amateurs and the FCC as Amateur license applications now are taking up to 12 weeks for final action. This is true even after special efforts (HR Report, August 1) to dig out. Unfortunately, no Amateur tickets were processed while the attempt to catch up on CB applications was underway.

Expansion Plans Provide Hope for the future. Included are a larger, faster computer and a 25% increase in personnel. Helping already are improved procedures and the new box numbers. Remember, address your Amateur applications to Box 1020, Gettysburg, Pennsylvania 17325.

SIX-METER AMATEUR BAND may be in trouble according to Prose Walker's comments at the Texas VHF FM Society's convention. Prose seems to feel that there's a definite push on to add channel 1 to the VHF TV spectrum, and channel 1 is 6 meters! The Channel 1 agitation may be an offshoot of a proposal made earlier this year by a Dallas consulting firm in response to Docket 20264, which pertains to radio callbox systems in the 72-74 MHz range, suggesting that those four MHz be added to two MHz from the six-meter band to create a new TV channel.

RTTY ENTHUSIASTS are warned that parts for Teletype Models 14, 15, 19 and 20 are going to become harder to get in the near future. Teletype Corp. has announced they'll stop accepting orders for all replacement parts for those models on December 1, 1975, so better order your spares now.

Questions Or Orders can go to Teletype, 5555 Touhy Avenue, Skokie, Illinois 60076, Attn: R.A. Morton, Dept. 3121 — phone (312) 982-2168. Thanks to W8KAJ.

AMSAT QSL BUREAU MANAGER WA1EHF has made a sudden move to California and plans to move the QSL bureau out there as soon as he has a permanent address. In the meantime, WA1EDX will be filling in the void for Dennis and the 288 Grand Street, Bridgeport, Connecticut 06604 address is still valid.

Satellite Use for location of downed aircraft has been proposed, and AMSAT has been asked to participate in feasibility studies. Anyone interested — particularly members in the mid-Atlantic (Washington) area — should contact AMSAT.

OSCAR AND THE HAM, a new video tape copyrighted by the ARRL, has been released for viewing on local PBS stations. Anyone interested should contact their local station and request that they run it.

Help Is Needed in making video tape copies. If you can give any assistance, please get in touch with ARRL Headquarters.

"HOT" HAM GEAR does show up and it pays to be able to prove positive ownership when it does. WB9EBO found his Standard 826 and synthesizer stolen from his home last spring for sale at Hamfesters' hamfest near Chicago, kept an eye on them while W9JZK called the Cook County Sheriff's Police for assistance. Gerry's call, electric penciled inside the chassis, left the seller (a non-ham who had "bought them from some guy at another hamfest") without an argument.

EUROPEAN BOUND U.S. HAMS should seriously consider taking along a hand-held tuned up for appropriate repeaters on the low end of two meters. W9JUV heard lots of activity in Germany and England on a tunable receiver during a two-week trip in August, and temporary operating permits for many parts of Europe are much easier to get than are their equivalents here.

B. L. DRAKE COMPANY FOUNDER and president Bob Drake passed away July 28th after a long illness. Bob, W8CYE, founded the R.L. Drake Company in 1942 and was active in the successful business until recently. His son Peter has been elected president and promises to continue the traditions of this Amateur-oriented firm. No policy or personnel changes are anticipated in the near future.

JOSEPH JOHNSON, W3GG0, has been named Chief, Rules and Legal Branch of the Amateur and Citizens Division of the FCC effective August 17. Joe replaces John Johnston, K3BNS. This is an important position and we are glad to again see an Amateur in this chair.
This is one of the great features of the Atlas 210x/215x, the most versatile transceivers. It takes only seconds to slip the 7 pound midget out of the AC console, plug it into the mobile mount, and you're right back in the QSO.

It's only a midget in size, but in performance the rig is a real giant. With a solid 200 watts P.E.P. input you can easily work anyone you can hear, and the receiver offers you the ultimate in sensitivity, selectivity, and immunity to overload.

You have full coverage of all bands (except 10 meters, where coverage is 28.4 to 29.4 MHz). The Model 210x covers 10, 15, 20, 40, and 80 meters. The 215x covers 15, 20, 40, 80, and 160 meters.

**MODEL 210x**
- or 215x ................ $649

**MODEL 220-CS**
- AC CONSOLE ........... $139

**MODEL 200-PS**
- PORTABLE AC SUPPLY . $95

**PLUG-IN MOBILE MOUNT** . $44

For complete details see your Atlas dealer, or drop us a card and we'll mail you a brochure with dealer list.

"SEE YOU AT SAROC '76!"
receiver
noise figure
sensitivity and
dynamic range —
what the numbers mean

A complete discussion of receiver sensitivity, intermodulation distortion, cross modulation and gain compression, and what they mean in terms of performance

When it came to receivers, the earliest amateur operators were concerned primarily with sensitivity and experimented almost endlessly with different types of crystals, trying to find the one that was the most sensitive. Then came DeForest’s Audion, and Armstrong’s regenerative detector, and amateurs who could afford the tubes found they had all the sensitivity they could use. However, as the hobby grew, and more and more amateurs started populating the band below 200 kHz, the simple regenerative detector simply wasn’t up to the task. Selectivity, with simple tuned input circuits, was practically nonexistent, and the regenerative detector hopelessly overloaded in the presence of strong signals.

In the early 1920s amateurs worked to improve their tuners, but even the so-called “low-loss” tuners were only marginally acceptable. Although several superheterodyne designs were described in the amateur magazines, it wasn’t until low-cost, commercial i-f transformers became available in the late twenties that the superhet saw widespread amateur use. Selectivity against interfering signals was still a problem, however, and James Lamb revolutionized receiver design in 1932 with his “single-signal” CW circuit which used an i-f stage with extremely high selectivity — provided by regeneration or a simple crystal filter.

The single-signal, single-conversion superhet of the late 1930s suffered from poor rf image response at the higher frequencies, but it wasn’t too severe on 14 MHz and few amateur receivers of the day, in fact, tuned much above 18 or 20 MHz (15 meters was not yet assigned to amateur use and most 10-meter operators used specialized receivers or converters). When the 10- and 15-meter bands opened up after the war, however, the poor rf image response of the
single-conversion superhet with a 455-kHz i-f had to be faced — it was solved by going to a double-conversion layout with a first conversion to 2 or 3 MHz to minimize rf image response, and a second conversion to 455 kHz or lower for adjacent channel selectivity.

Although amateur radiotelephone operation in the 1930s was relatively limited, the huge growth of a-m activity after the war demanded improved adjacent-channel phone selectivity. While the crystal filter provided excellent selectivity for CW operation, it was of little or no use on a-m or ssb and some phone operators started using a Q5er — an outboard 80-kHz i-f strip — for improved phone selectivity. This led to the triple-conversion superhets which were the rage of the 1950s.

As pointed out by Goodman, however, the multiple-conversion design had many shortcomings, including the large number of stages between the antenna and the high-selectivity i-f which made it practically impossible to attenuate strong, adjacent signals. And, with at least three oscillators running at the same time, it was difficult to avoid the many spurious signals which were generated within the system. He advocated a return to the single-conversion superhet using highly-selective, high-frequency, crystal lattice filters which were just then becoming commercially available.

The 1960s saw a return to single-conversion designs, the use of high-frequency, crystal-lattice filters and the widespread use of semiconductors. With modern devices receiver sensitivity was no longer limited by the rf amplifier (or mixer) stage, but by the external galactic and man-made noise. Cross modulation and overload, on the other hand, were becoming a serious problem as more and more amateurs started using high-power linears and large, directive antennas. Modern communications receivers, therefore, in addition to meeting stringent frequency accuracy, stability, sensitivity, and selectivity requirements, must provide freedom from cross modulation, intermodulation distortion and blocking. Some modern, solid-state solutions to these design goals were discussed recently by Rohde.

The specifications for a typical modern communications receiver might list sensitivity of 0.5 μV for 10 dB signal-plus-noise-to-noise (S+N/N) ratio, intermodulation distortion of −65 dB, “wide” dynamic range, and “virtual elimination” of overload from adjacent signals.

However, is 0.5 μV sensitivity for 10 dB S+N/N adequate for operation on the high-frequency bands? For satellite communications on 10 meters? What is −65 dB intermodulation distortion in terms of signal strength? “Wide dynamic range” and “virtual elimination of overload” are obviously advertising superlatives without definition but what, exactly, can you expect from a high-quality, modern receiver design? Perhaps, if these performance data were defined,
and amateurs understood what they meant, manufacturers would be encouraged to use no-nonsense numerical data. Only then can amateurs compare the dynamic range and cross-modulation performance of one receiver against that of another.

**sensitivity**

The minimum usable signal or sensitivity of a receiver is determined by the noise in the receiver output. This can be noise generated within the receiver, thermal noise generated by losses in the transmission line, or atmospheric, man-made or galactic noise picked up by the antenna. As shown in fig. 1, external noise sources are likely to be the limiting factor up to 100 MHz or so. In urban areas man-made noise predominates and measurements indicate the average level of man-made noise in suburban areas is about 16 dB lower. In a quiet, rural location which has been chosen with care the man-made noise may be near the galactic noise level, but few amateurs are so fortunate.

Atmospheric noise usually predominates in quiet conditions at frequencies below about 20 MHz and is produced by lightning discharges so the level depends upon a number of variables including frequency, weather, time of day, season and geographical location. This type of noise is particularly severe during rainy seasons near the equator and generally decreases at the higher latitudes. More complete data on high-frequency atmospheric noise is given in reference 5.

Galactic or cosmic noise is defined as rf noise caused by disturbances which originate outside the earth or its atmosphere. The primary causes of this noise, which extends from 15 MHz well into the microwave region, are the sun and a large number of noise sources distributed chiefly along the Milky Way. Solar noise can vary as much as 40 dB from “quiet” sun levels (low sunspot activity) to periods of “disturbed” sun (high sunspot activity). Galactic noise from the center of the Milky Way is about 10 dB below the noise from a “disturbed” sun, whereas noise levels from other parts of the galaxy can be as much as 20 dB lower. This is important in satellite communications and will be discussed later.

**thermal noise**

The free electrons in any conductor are in continuous motion — motion that is completely random and is the result of thermal agitation. The effect of this electron motion is to cause minute voltages which vary in a random manner to be developed across the terminals of the conductor. Since this phenomenon was first demonstrated by J. B. Johnson in 1928, thermal noise is sometimes known as Johnson noise. At the same time, H. Nyquist showed, on the basis of the statistical theory of thermodynamics, that the mean square noise voltage generated in any resistance can be expressed as

$$e^2 = 4kTB$$  \(1\)

where $e^2$ = mean square noise voltage  
$k$ = Boltzmann's constant = $1.38 \times 10^{-23}$ joules/°K  
$T$ = absolute temperature, °K  
$B$ = bandwidth, Hz  
$R$ = resistance, ohms

Note that the noise voltage is dependent upon the bandwidth across which it is measured. This implies that noise is evenly distributed across all frequencies which, for all practical purposes, it is. Although noise bandwidth is not precisely the same as the 3-dB bandwidth of a receiver, in modern receivers with high skirt selectivity the 3-dB bandwidth can be used in eq. 1 with little error.

The equivalent circuit of any impedance as a source of noise voltage is

*At extremely high frequencies statistical mechanics is no longer valid, and eq. 1 must be revised on the basis of quantum theory. This equation is valid, however, to at least 6000 GHz."
shown in fig. 2A. Note that the thermal noise voltage is dependent only on the resistive component and is independent of any reactance in the circuit. As might be expected, maximum noise power is transferred from a thermal noise source when the load impedance presents a conjugate match to the source impedance. This is represented in fig. 2B where the load resistance, $R_L$, is equal to the source resistance. Since $R = R_L$, the noise voltage developed across the load is $e/2$, and from Ohm's law

$$ P = \frac{E^2}{R} = \left(\frac{e}{2}\right)^2 = \frac{e^2}{4R} \text{ watts} \quad (2) $$

Substituting the value of $e^2$ from eq. 1 into eq. 2, the power which can theoretically be transferred under such conditions is called the available noise power and is given by

$$ P_n = kTB \quad (3) $$

The factor of $4R$ has cancelled out so the available noise power does not depend upon the value of the resistance. This is significant because it means that the available noise power of any resistor (or any noise source), if measured over the same bandwidth, can be represented by a resistor at temperature $T$. Thus, every noise source has an equivalent noise temperature.

The actual noise power dissipated in the load resistance may be affected by loss in the connecting leads, noise power generated in the load resistor itself, or a less than perfect match to the original resistance. This property is sometimes used in low-noise uhf amplifiers by creating a deliberate (but carefully determined) mismatch between the input termination and the detection device so that something less than the available termination noise power is coupled into the detector.

**signal-to-noise ratio and receiver noise figure**

The relation of signal amplitude to noise is commonly referred to as the signal-to-noise (S/N) ratio. Unfortunately, this ratio has not been well standardized and is often used interchangeably to mean the ratio of rms signal voltage to rms noise voltage, the ratio of peak signal voltage to peak noise voltage and, in pulse systems, the ratio of peak signal power to average noise power. Therefore, when discussing S/N ratio, it's important to determine exactly which ratio is being referred to.

Although the minimum discernible signal (MDS) that can be heard above the receiver noise level is sometimes used as an indication of receiver sensitivity, it is extremely subjective because it differs many dB from measurement to measurement, and from one operator to another (some experienced weak-signal operators can detect signals as much as 20 dB below the noise level while other operators may have difficulty discerning signals which are equal to the noise level).9

Receiver sensitivity has also been defined in terms of a signal-to-noise ratio of unity (signal equals noise)* or equivalent noise floor, but this is difficult to measure unless you have a calibrated signal generator and a spectrum analyzer. Noise figure or noise factor, on the

*This is sometimes erroneously referred to as tangential sensitivity. Tangential sensitivity, however, corresponds to a signal-to-noise ratio of 6.25 and is about 8 dB higher.10
other hand, is less susceptible to measurement errors than sensitivity and, since its introduction in 1944 by Friis, it has become the accepted figure of merit for receiver sensitivity. Noise figure, $NF$, is simply noise factor, $F$, expressed in dB.

$$NF = 10 \log F \text{ (dB)} \quad (4)$$

The concept of noise factor allows the sensitivity of any amplifier to be compared to an ideal (lossless and noiseless) amplifier which has the same bandwidth and input termination. As far as noise is concerned, that part of a receiver between the antenna and the output of the i-f amplifier can be regarded as an amplifier. The fact that the mixer stage shifts the frequency of the noise does not change the situation — it merely causes the noise to lie in a different place in the spectrum from the input noise. The only exception is when the receiver has poor rf image rejection. In this case the noise figure of the receiver is 3 dB worse than it would be if the same receiver had good rf image rejection because the image noise appears at the output along with noise associated with the desired received frequency. This effectively doubles the noise at the output of the i-f amplifier.*

The noise factor, $F$, of a receiver is defined as

$$F = \frac{S/N \text{ (ideal receiver)}}{S/N \text{ (practical receiver)}} = \frac{S_i/N_i}{S_o/N_o} \quad (5)$$

$S_i =$ available signal input power  
$N_i =$ available noise input power  
$S_o =$ available signal output power  
$N_o =$ available noise output power

Using this definition, it can be seen that an ideal receiver adds no noise to a signal so its output signal-to-noise ratio is the same as that at the input and the noise factor, $F = 1$.

Since the available noise input power, $N_i$ is defined as $k T_o B$ in eq. 3, and the power gain of the system, $G = S_o/S_i$, eq. 5 can be rewritten as

$$F = \frac{N_o}{G k T_o B} \quad (6)$$

Where $T_o$ is 290° kelvin (IEEE definition). With the receiver noise factor defined in terms of noise output power, $N_o$, power gain, $G$, and noise input power, $k T_o B$, noise factor can be easily correlated to receiver sensitivity. Consider the case where the output signal-to-noise ratio, $S_o/N_o$, is unity

$$S_o = N_o$$

*The noise figure is always defined at the input of the final detector (i-f output) because the noise output of a detector (but not of a mixer) is affected by the presence of a signal. An fm signal, for example, will suppress weak noise but will be suppressed itself by strong noise.
For this specialized case, eq. 6 can be rewritten

\[ F = \frac{S_i}{kT_o B} \] (7)

When the temperature is 290°K and the bandwidth is in kHz, \( kT_o B = 4 \times 10^{-15} \) mW per kHz. Rewriting eq. 7 in terms of dBm (dB referenced to 1 mW)

\[ S_i = 10 \log kT_o + 10 \log B + NF \] (8)

where 

\[ E = \sqrt{RP} \] (9)

where \( E \) is in volts, \( R \) is resistance in ohms and \( P \) is power in watts. Since -123 dBm is \( 5.01 \times 10^{-16} \) watts, -123 dBm is equivalent to 0.16 \( \mu \)V across a 50-ohm input termination. However, for a matched signal source, as shown in fig. 4, where the source resistance, \( R_s \), is equal to the load resistance, \( R_L \), the source voltage must be twice the voltage across \( R_L \) because of the voltage-dividing effect of the two series resistors in the network. For a **matched** 50-ohm source, therefore, an input signal of -123 dBm (10 dB greater) would be required for a 10 dB S/N ratio.*

To convert dBm to microvolts, recall that

\[ E = \sqrt{RP} \] (9)

*This is the signal-to-noise ratio in ssb and CW reception. The S/N ratio of a-m and nbfm signals is somewhat less because a-m (and nbfm) detection use only the envelope as a useful output and the S/N ratio must be reduced by a factor which is related to percentage of modulation (or modulation index).
Because of this two-to-one voltage-dividing effect, you must be very careful when comparing the sensitivity of one receiver against that of another. An input of +119 dBm, for example, implies an input directly at the receiver terminals and is 0.25 μV rms across 50 ohms. Sensitivity, on the other hand, implies the use of a matched signal generator so sensitivity of 0.25 μV corresponds to an input of -125 dBm. This is a 6 dB difference. Since most amateur receiver manufacturers tend to use sensitivity specifications, there is no advantage, but the difference must be considered when you calculate the receiver noise figure and dynamic range. In this article inputs will be stated in dBm as this eliminates the 6 dB conversion factor — table 1 can be used to convert to sensitivity.*

cascaded stages

A relatively simple equation for the noise factor of a receiving system, in terms of the individual stage gains and noise factors is

\[ F_T = F_1 + \frac{F_2 - 1}{G_1} + \frac{F_3 - 1}{G_1 G_2} \]  

(10)

Note that all terms are in power ratios. If the gain of the first stage is high, and the noise factor of the second stage is low, the overall system noise factor is determined primarily by the first stage and the third term of eq. 10 may be dropped.

For example, consider the block diagram of the first three stages of a typical vhf receiving system shown in fig. 5. The overall system noise factor is

\[ F_T = 1.59 + \frac{4 - 1}{10} + \frac{10 - 1}{10 \cdot 16} \]

\[ = 1.59 + 0.3 + 0.056 = 1.946 \]

\[ NF_T = 10 \log 1.946 = 2.9 \text{ dB} \]

For this receiver the overall system noise figure is 0.9 dB higher than that of the preamplifier alone. Raising the preamplifier gain to 13 dB or dropping the noise figure of the second stage to 4 dB \((F = 2.5)\) would reduce the system noise figure to approximately 2.45 dB \((F = 1.75)\). Depending on the frequency and the application, this may be a worthwhile improvement.

noise temperature

It is often convenient when working with very low noise uhf and microwave receivers to represent the noise figure of the receiver as an equivalent noise temperature. This is because the noise temperature of a receiving system varies over the range from 0° to 174°K as the noise factor varies from 1.0 to 1.6 (0 to 2 dB noise figure) and noise calculations using equivalent noise temperatures will provide better accuracy.

As mentioned above, the noise figure of an ideal receiver is 1, so the component of receiver noise figure which is due to internally generated noise, \(N_r\), is

*The usual procedure for measuring receiver sensitivity is to place a 6 dB attenuator between the signal generator and the receiver. Receiver sensitivity can then be read directly from the signal generator's calibrated output attenuator.
Therefore
\[ N_r = (F - 1) GkT_o B \] (11)
The internally generated noise, \( N_r \), can be represented by a noise power, \( GkT_o B \), where \( T_o \) is the equivalent noise temperature. Substituting into eq. 11, this equivalent noise temperature can be expressed in terms of the reference noise temperature, \( T_o = 290°K \).
\[ T_r = (F - 1) T_o \] (12)
Eq. 12 can be easily rearranged to express noise factor as a function of the receiver noise temperature, \( T_r \), and the reference noise temperature, \( T_o \):
\[ F = 1 + \frac{T_r}{T_o} \] (13)
Although noise temperature is seldom used by amateurs, it is a more basic unit than noise factor and is actually easier to deal with, both in understanding concepts and making practical noise calculations. For a more complete discussion of noise temperature, see reference 12.

**transmission lines**
The transmission line's contributions to receiver noise come from a common source: line losses. The first of these is the more obvious. When a signal travels down a lossy transmission line, the signal is attenuated. This reduces the signal-to-noise ratio and is equivalent to increasing the noise factor of the receiver. This increase can be calculated by introducing a loss factor, \( L \), which is the loss of the cable expressed as a power ratio.

The second effect is due to the noise factor of the transmission line. The fact that the line has losses implies that there is a loss resistance associated with it (which is distinct from characteristic impedance). Since the line is warm, it generates noise due to thermal agitation. The noise factor of the line, \( F_t \), is related to the loss factor, \( L \), and the physical temperature of the line, \( T_t \), by the following equation
\[ F_t = \frac{(1/L - 1) T_t}{290} + 1 \] (14)
The degradation of the receiver noise figure due to transmission line contributions may be calculated by considering the transmission line and the receiver as cascaded stages and using a form of eq. 10
\[ F_{tr} = F_t + \frac{F_r - 1}{L} \] (15)
where \( F_{tr} \) = noise factor of the receiver and transmission line, \( F_r \) = noise factor of the receiver, \( F_t \) = noise factor of the transmission line, \( L \) = loss factor of the transmission line.

For example, a receiver with a noise factor of 4 (NF = 6 dB) is used with a transmission line which has a loss factor of 0.63 (2 dB loss). The physical temperature of the line is 300°K (\( I_t = 1.61 \)). What is the combined noise figure?
\[ F_{tr} = 1.61 + \frac{4 - 1}{0.63} = 6.37 \]
\[ NF_{tr} = 8.04 \text{ dB} \]

When line losses are low but receiver noise figures are 3 dB or greater, line loss is the predominate contributor to increased noise figure. When receiver noise figure is very low, the thermal effect predominates.

**antenna noise**
Of all the contributions to system noise, antenna noise is probably the least understood. Assuming the antenna is built of good conducting materials, it contributes virtually no thermal noise of its own to the receiving system. The noise power the antenna does deliver to the receiver depends almost entirely on
table 2. Performance of a receiver with 0.5 μV sensitivity for 10 dB S+N/N with 100 feet (30.5m) of RG-8A/U transmission line is shown in first two columns. Third column lists external available noise power for quiet receiving locations on each of the amateur bands. Fourth column shows receiver signal (50-ohms) required for 10 dB S+N/N on each of the bands (based on external noise). Last column lists acceptable noise figure for each of the bands (see text). Bandwidth = 2.1 kHz.

the temperature and other physical characteristics of the material lying in the antenna’s field of view. A 432-MHz moonbounce receiving antenna looking out into space, for example, may deliver only as much noise power as a resistor at 10⁰K (noise factor = 1.03). If this same antenna is rotated so that the warm earth comes into its field of view, the antenna noise temperature would rise to about 300⁰K (noise factor = 2).

A ten-meter Oscar receiving antenna which is pointed into “cold” space, on the other hand, will see a noise temperature of about 10,000⁰K minimum (noise factor = 35). Pointed at the horizon, however, the antenna noise temperature may be ten or fifteen times higher, depending upon the amount of man-made noise.

There is little that can be done to improve the situation of a terrestrial radio circuit, but an antenna that looks at the sky, such as a satellite antenna, deserves careful design. This is because the effect of the earth is still present, and any sidelobe that sees the earth will pick up thermal noise. This is sometimes quite serious and sidelobes are of major concern in many deep-space communications and radio astronomy systems. Careful attention to antenna design with respect to sidelobes can provide antenna temperatures significantly under 50⁰K, while poor design can result in much higher values.

minimum usable sensitivity

With an understanding of receiver noise factor and its relationship to signal-to-noise ratio, it’s now possible to determine the minimum usable sensitivity (MUS) of a receiving system, and how the performance of your own equipment affects your ability to receive weak signals. Let’s first consider that modern communications receiver mentioned earlier which had a specified sensitivity of 0.5 μV for 10 dB S+N/N ratio.*

From table 1 a 0.5 μV sensitivity for 10 dB S+N/N is equivalent to a sensitivity of -119 dBm in a 50-ohm system (-129 dBm noise floor). Assuming a bandwidth of 2.1 kHz, the noise figure of the receiver is about 11.8 dB (noise factor = 15.1). Assuming 100 feet

*A S+N/N ratio of 10 dB corresponds to a S/N ratio of 9.54 dB, a difference small enough to be neglected for all practical purposes. A S+N/N ratio of 3.5 dB, however, corresponds to a S/N ratio of about 0.9 dB, and the difference must be considered. S+N/N may be converted to S/N by using the relationship [(S+N/N) - 1] = S/N (in power ratios, not dB).
(30.5m) of RG-8A/U transmission line at 300°K, the noise factor at the antenna terminals may be calculated from eq. 15, and is shown in table 2 for the six high-frequency amateur bands, (calculated on the basis of 0.5 μV sensitivity for 10 dB S+N/N on all bands, which may be optimistic). Even at 28 MHz, where the line loss has increased the noise factor by 25 per cent, the system noise factor is still well below the available noise power seen by the antenna (see fig. 1).

At 50 MHz, however, the system is limited by receiver noise and a lower noise figure would be required for weak-signal work (system noise at 50 MHz in this example is about 2.4 dB higher than external noise for a quiet location). If the receiver was connected directly to the antenna terminals to eliminate transmission line losses the system noise figure would be essentially that of the receiver alone and a 0.5 μV signal would provide the desired 10 dB S+N/N ratio. Although 100 feet (30.5m) of RG-8A/U coaxial cable has only about 1.35 dB loss at 50 MHz, it degrades the noise figure sufficiently that the system is no longer limited by external noise sources. This points up the importance of using low-loss transmission lines (or mounting a receiving preamp at the antenna).

Assuming a quiet, rural location that is limited primarily by galactic noise down to about 18 MHz, and atmospheric noise below 18 MHz, what is the minimum usable receiver sensitivity for terrestrial communications?

As can be seen from table 2, rather poor receiver sensitivity is acceptable on 40, 80 and 160 meters because the external noise at these frequencies is very high. This also explains why the simple receivers of the 1920s were relatively successful. The high external noise levels also make it possible to use rather inefficient receiving antennas on the lower frequencies. It’s important to note that a 0.5 μV signal is of little practical use on 160, 80 or 40 meters because it would be buried in the noise level.

The required sensitivity on 20, 15 and 10 is not difficult to obtain with modern devices, but receivers which are optimized for the lower frequencies may not offer top performance on 10 meters. It should be pointed out that the “acceptable” noise figure in the last column of table 2, is somewhat arbitrary and is based on setting the receiver noise floor about 3 dB below the external noise floor. This is probably adequate 90 per cent of the time, but since noise varies randomly, a statistical analysis indicates there may be times when a lower noise figure may be desirable. However, it is generally agreed that a 10 dB noise figure is more than adequate up to 22 MHz and an 8-dB noise figure may occasionally prove useful on 10 meters. Why design a high-frequency receiver for extraordinary sensitivity when its performance is limited by external noise over which you have no control? A very sensitive receiver is more prone to intermodulation and cross-modulation effects, and these may be more important.

At vhf the external noise levels are much lower and low-noise receivers are required for good weak-signal performance. Since it’s relatively easy to build low-noise receivers for 50 MHz with modern semiconductors, there’s no excuse for being limited by system noise figure on this band. A receiver with a 5 dB noise figure at 50 MHz, for example, when used with 100 feet (30.5m) of RG-8A/U transmission line, will provide a system noise factor of 4.38 (NF = 6.4 dB) at the antenna terminals. This is well below the external noise.

The 144-MHz example in table 2 is hopelessly inadequate and represents at least 12 dB degradation over what can be obtained in practice. A receiver with a 1.5 dB noise figure on this band, when used with the 100 feet (30.5m) of RG-8A/U, will provide a system noise...
factor of 2.54 \((\sqrt{\text{NF}} = 4.1 \text{ dB})\) at the antenna terminals which is still inadequate. A transmission line with 0.7 dB loss would bring receiver noise figure within acceptable limits, but it might be easier and less expensive to install a low-noise preamp at the antenna.

As pointed out earlier, the noise temperatures of antennas that are pointed into space for satellite communications (or EME) are much lower than for terrestrial communications where the antenna is pointed at the horizon. This means that the receiver noise figures must be lower for maximum performance. Some parts of the sky are noisier than others due to the presence of noise sources, but the noise figure of the receiver should ideally be low enough that the system is galactic-noise limited. Following are the receiver noise figures to shoot for when designing receivers or converters for satellite communications on vhf.

These figures are based on a 2.1-kHz bandwidth and assume a lossless transmission line. For more accurate calculations at low noise figures, the use of noise temperatures is recommended.

Although the topic of noise figure measurement is beyond the scope of this article, the simplest method of making the measurement is to compare receiver noise to the noise generated by a temperature-limited vacuum diode. This technique is easily applied in the home workshop and has been discussed many times in the amateur radio magazines.14,15,16 Guentzler also described a noise measuring system which used a pilot lamp as a noise source.17

**Intermodulation distortion**

Amplitude distortion occurs in an amplifier when the magnitude of the output signal is not exactly proportional to the input signal. Although amplifiers can be designed to be nearly perfectly linear over a portion of their operating range, every amplifier has nonlinearity which can cause distortion products or harmonics of the driving waveform. **Intermodulation distortion** or IMD is a type of amplitude distortion which occurs when a nonlinear amplifier is driven by more than one discrete frequency. Although the discussion here is limited to IMD in receivers, this is the same distortion which is used to define the linearity of ssb linear power amplifiers.

When an rf signal with varying amplitude is passed through a nonlinear device, many new products are generated. The frequency and amplitude of each component can be calculated mathematically since the nonlinear device can be represented by a power series expanded about the zero-signal operating point.18

Although many products are generated, the ones of primary concern are the second and third. This can be demonstrated with a two-tone signal with outputs at \(f_1\) and \(f_2\), 14001 and 14003 kHz.

\[
\begin{align*}
f_1 & = 14001 \\
f_2 & = 14002 \\
2f_1 & = 28002 \\
2f_2 & = 28004 \\
3f_1 & = 42003 \\
3f_2 & = 42006
\end{align*}
\]

Although each of the harmonics fall well outside the passband of a receiver which is tuned to pass 14001 and 14002 kHz, the harmonics mix together to produce intermodulation products which do fall within the passband. The third-order products consist of

\[
\begin{align*}
2f_1 - f_2 & = 14000 \text{ kHz} \\
2f_2 - f_1 & = 14003 \text{ kHz}
\end{align*}
\]

The fifth-order products consist of

\[
\begin{align*}
3f_1 - 2f_2 & = 13999 \text{ kHz} \\
3f_2 - 2f_1 & = 14004 \text{ kHz}
\end{align*}
\]

The output spectrum is shown in fig. 6. Unless the nonlinearity of the amplifier
fig. 6. Third- and fifth-order intermodulation products generated by input signals at 14001 and 14002 kHz. In receiver stages fifth-order IMD is usually small enough to be neglected.

is particularly severe, fifth-order IMD is not usually a problem and can be ignored in receiver applications.

Although the IMD distortion products which are generated by two discrete frequencies are used here because

\[-f_R 1 \pm f_L\]. Third-order intermodulation products also occur at \((2f_R 1 - f_R 2)\) and \((2f_R 2 - f_R 1)\). Two input frequencies at 14210 and 14230 kHz, for example, with a 5.2-MHz local oscillator (9 MHz i-f), will produce two-tone, third-order intermodulation products at 8990 and 9050 kHz (i-f passband) and 14190 and 14250 kHz (rf passband).

Third-order IMD is measured in the laboratory with a spectrum analyzer using the test setup in fig. 7. However, the concept of the third-order intercept is finding increased use to describe the IMD response of mixers, and can also be used to describe the linearity of amplifiers.* The third-order intercept is the theoretical point where the two-tone, third-order response is exactly equal to

they're easy to visualize, exactly the same sort of thing occurs with complex speech waveforms.

In a receiver rf amplifier or mixer stage IMD may be caused by two adjacent CW signals or by a ssb signal. Furthermore, in a mixer where the input must be wideband (such as the double-balanced mixer which is currently finding wide use), two input signals, \((f_R 1\) and \(f_R 2\)) may mix with the local oscillator \(f_L\) to produce in-band, two-tone, third-order intermodulation products \((2f_R 1 - f_R 2) \pm f_L\) and \((2f_R 2 - f_R 1) \pm f_L\)...

*Class A amplifiers. Linear class AB or B amplifiers often exhibit two-tone, third-order intermodulation products which follow an S-shaped curve that both increases and decreases with additional input signal level so they cannot be compared by the intercept point method.

In addition, the intercept point permits comparison of amplifiers and mixers where the intermodulation specifications are given at different two-tone levels. Once the intercept point is known, you can calculate the two-tone, third-order response at any input level by simply remembering that every 1-dB change in the two-tone input produces a 3-dB change in the third-order output. With this information it is possible to predict the maximum rf input level which is allowable.

With each 1 dB decrease in the \(f_R\) input level, for example, the third-order

fig. 7. Block diagram of the test setup for evaluating the IMD performance of an amplifier or mixer with a spectrum analyzer.
product is decreased an additional 2 dB. As shown in fig. 8, a high-level double-balanced mixer will suppress third-order products about 65 dB when both signals are at zero dBm (224 mV across 50 ohms) and 85 dB when both input signals are at -10 dBm (71 mV across 50 ohms). The third-order intercept point for these mixers is +27.5 dBm, relative to the output. Relative to the input, the intercept point is at +32.5 dBm. This is 17 dB higher than the intercept point for a low-level double-balanced mixer such as the Minilabs SR1A or Anzac MD108. The 3-dB compression point shown on the graph is a combination of both conversion compression and desensitization.

intercept point

The third-order intercept point, IP, can be calculated from the relationship

\[ IP = \frac{1}{2}(P_o - P_d) + P_i \quad (16) \]

where:
- \( IP \) = third-order intercept, dBm
- \( P_o \) = desired output, dBm
- \( P_d \) = third-order distortion products, dBm
- \( P_i \) = input power, dBm

Since the third-order IMD is defined as \( (P_o - P_d) \), eq. 16 can be rewritten as

\[ IP = \frac{1}{2}IMD + P_i \quad (17) \]

For the spectrum display shown in fig. 9, for example, the third-order intermodulation distortion products with two input signals of 4 mV (-67 dBm) are 80 dB down, and the third-order intercept is

\[ IP = 0.5 \cdot 80 - 35 = 45 \text{ dBm} \]

Most amateurs don't have spectrum analyzers, but if good intermodulation distortion information is provided on the receiver data sheet, the intercept point can be easily calculated with eq. 17 (in all too many cases, however, amateur receiver manufacturers ignore IMD completely, and when they do provide IMD data, it is incomplete). However, assume the specifications for an amateur-band receiver list -75 dB IMD for an input of 1 mV (-47 dBm). The third-order intercept is

\[ IP = 0.5 \cdot 75 - 47 = -9.5 \text{ dBm} \]

Once the intercept point is known, the IMD performance at any input level can be found by rearranging eq. 17.

\[ IMD = 2(IP - P_i) \quad (18) \]

For an intercept point of -9.5 dBm, for example, the IMD at various input levels is shown below.

<table>

</table>

The superiority of this receiver is obvious — for all but the strongest signals the IMD products are at or below the receiver noise level. Assuming a 10 dB noise figure and 2.1-kHz bandwidth, an input signal of −23.7 dBm (14.7 mV across 50 ohms) will produce IMD products just equal to the noise level. In the receiver with an intercept point at −9.5 dBm, however, the IMD products are already 3 dB greater than the noise with an input of −49 dBm (800 µV). This will be discussed further under the subject of dynamic range.

**double-balanced mixers**

Often a mixer data sheet does not specify the third-order intercept point, but a rule-of-thumb estimate can be easily made by examining the 1-dB compression point. As the rf input is increased, the i-f output should follow in a linear manner. However, after a certain point, the i-f output increases at a lower rate until the mixer output becomes fairly constant. The point at which the i-f output deviates from the linear curve by 1 dB is called the 1-dB compression point. At this point the conversion loss is 1 dB greater than it was when the rf input was smaller.

The importance of the 1-dB compression point is its utility in comparing the dynamic range, maximum output and two-tone performance of various double-balanced mixers. As a rule of thumb, the third-order intercept point is approximately 10 to 15 dB higher than the 1-dB compression point (about 15 dB at the low frequencies and 10 dB at higher frequencies). This is shown in fig. 10.

To properly use a double-balanced mixer, it is necessary to relate the two-tone input and third-order output levels to avoid generating excessive distortion which would compromise the final design. This is equally valid for amplifiers. Also important, but not as obvious, is the effect higher operating frequencies have on the double-balanced mixer's two-tone, third-order distortion characteristics. Performance is usually better at the lower frequencies and drops off as frequency is increased. For typical high-frequency double-balanced mixers with a maximum frequency specification of 500 MHz, performance starts to fall off somewhere between 50 and 100 MHz.

As discussed by DJ2LR on page 26, it is now possible, using a double-
balanced mixer in the front end, to build high-frequency communications receivers with a third-order intercept at +30 dBm. Using the rule of thumb that the 1-dB compression point is 15 dB below the intercept point, 1-dB compression occurs at an input of approximately +15 dBm or 1.25 volts across 50 ohms.

By comparison, the 1 dB compression point of many commercial amateur receivers is in the vicinity of -20 dBm (22 mV across 50 ohms) and some solid-state receivers with bipolar rf amplifiers go into compression at -40 dBm (2 mV across 50 ohms).

cross modulation

Another type of amplitude distortion which can occur in tuned amplifiers is cross modulation. This is related to IMD and is produced when the modulation from an undesired signal is partially transferred to a desired signal in the passband of the receiver. The 3-dB compression point in fig. 8 describes the start of cross-modulation effects.

The cross-modulation effect is independent of the desired signal level and is proportional to the square of the undesired signal amplitude. Because of this relationship, an rf attenuator which lowers the signal level at the input to the receiver may provide a great improvement in cross-modulation performance. A 6 dB attenuator at the receiver input terminals, for example, will reduce cross modulation by 12 dB. If the desired signal is at least 6 dB above the level at which the receiver provides a satisfactory S/N ratio this results in a marked improvement in received signal quality.

Cross modulation is measured in the laboratory by setting one signal generator to deliver a CW output and another generator is set up for 30% amplitude modulation. The output of the a-m generator is increased until 1% modulation appears on the CW signal as measured with a spectrum analyzer. This represents a cross-modulation ratio of about 30 dB (cross-modulation level 30 dB below the reference level).

Cross modulation is related to the intercept point by the relationship

\[ \frac{m}{m'} = \left( \frac{P_{ip}}{4P_c} \right) - \frac{1}{2} \]  \hspace{1cm} (19)

\[ m/m' = \text{ratio of cross modulation transferred from a large signal to a smaller one} \]

\[ P_{ip} = \text{intercept point power} \]

\[ P_c = \text{interfering signal power} \]

Cross modulation in dB is simply

\[ m/m' (dB) = 20 \log (m/m') \]  \hspace{1cm} (20)

In fig. 11 cross modulation is plotted against the difference between the intercept point and the cross-modulating signal in dBm. Cross modulation of 30 dB, for example, corresponds to 21 dB difference between the intercept point and the signal producing the cross modulation. For a receiver with an intercept point at +30 dBm, a modulated input signal at a level of +9 dBm (630 mV...
across 50 ohms) will produce 30 dB cross modulation. For a receiver with an intercept point at −9.5 dBm (the more usual case), an interfering signal level of −30.5 dBm (6.7 mV) will produce 30 dB cross modulation.

**gain compression**

When a receiver is tuned to a weak signal, a strong, adjacent signal may cause an apparent decrease in receiver gain. This is called *compression or desensitization* and occurs when the input voltage from the undesired signal is large enough to exceed the bias on an rf amplifier or mixer and drives the base (or grid) into conduction. This reduces gain, as shown by the compressed curve of fig. 8, and increases distortion. The rectified base (or grid) current can also be coupled back to the receiver’s agc system which results in a further reduction in overall receiver gain.

Compression is measured by setting one signal generator to produce a CW signal and another generator, at a given frequency spacing, is adjusted to depress the desired signal a certain amount, usually 3 dB. Like cross modulation, however, a compression specification has little meaning if the frequency separation between the two signals is not specified.

Since both cross modulation and compression are caused by strong, undesired signals which are adjacent to the receiver passband, they can be controlled to a certain extent by the selectivity at the front end of the receiver. High receiver sensitivity, of course, is the antithesis of good cross-modulation and compression performance — this reinforces the argument for receiver noise figures on the order of 10 dB for the high-frequency range.

**dynamic range**

The front end of a receiver is subjected to a multiplicity of input signals which tend to intermodulate to produce a level of distortion products which is dependent on the magnitude of the incoming signals. Therefore, the upper end of a receiver’s dynamic range is defined by the input signal level which produces third-order IMD products just equal to the receiver’s noise level.

At the lower end dynamic range is limited ultimately by the noise figure of the receiver. Also important, however, is the way the receiver handles weak signals. Some linear rf amplifiers and mixers give good performance in the middle of their operating range but exhibit transfer curves that introduce considerable distortion at low signal levels. With proper design, however, this is not a problem, and the dynamic range of a receiver is usually defined as the *spurious-free dynamic range* where the maximum input signal is as defined above and the minimum input signal is at the noise floor of the receiver (eq. 8).

\[
DR = 2/3 (IP - No)
\]  
(21)

where \(DR\) = spurious-free dynamic range, dB  
\(IP\) = intercept point, dBm  
\(No\) = receiver noise floor, dBm

The dynamic range of a receiver is important because it allows you to directly compare the strong-signal performance of one receiver against that of another. On today’s crowded bands, and the high incidence of kilowatt transmitters and directive antennas, strong-signal performance is usually much more important than sensitivity. Although dynamic range can be used as a figure of merit, it’s also useful to know the maximum input signal level, \(P_l(max)\), which will produce third-order IMD products just equal to the noise level. This can be calculated from:

\[
P_l(max) = 1/3(2IP + No)
\]  
(22)

\(P_l(max)\) = maximum input signal, dBm  
\(IP\) = intercept point, dBm  
\(No\) = receiver noise floor, dBm

* Derivation of eq. 16 through eq. 22 will be sent to interested readers upon receipt of a self-addressed, stamped envelope.
For example, assuming a noise figure of 10 dB and 2.1-kHz bandwidth, the spurious-free dynamic range and maximum input signal of a receiver with an intercept point at +30 dBm are

\[
DR = 2/3[30 - (-131)] = 107.3 \text{ dB}
\]

\[
P_{i(max)} = 1/3[2\cdot30 + (-131)] = -23.7 \text{ dBm}
\]

Thus, the IMD products will be well below the noise level for all input signals below -23.7 dBm (14000 \(\mu\)V or about S9+43 dB)! As a comparison, consider a receiver with a third-order intercept at -9.5 dBm (10 dB noise figure, 2.1-kHz bandwidth):

\[
DR = 2/3[-9.5 - (-131)] = 81 \text{ dB}
\]

\[
P_{i(max)} = 1/3[2(-9.5) + (-131)] = -50 \text{ dBm}
\]

With this receiver the distortion products are equal to the noise level with an input signal of about 710 \(\mu\)V or S9+17 dB. This may represent adequate strong-signal performance if you live out in the country, but it's doubtful. If you live in an urban area, you'll have a lot of trouble digging weak signals out of the morass of IMD products which effectively raise the noise floor of the receiver.

A graph of intercept point vs dynamic range and maximum input signal is presented in fig. 12 for a receiver with a 10 dB noise figure and 2.1-kHz bandwidth (typical for modern amateur communications receivers).

**Summary**

Although modern amateur receivers are no longer performance limited by noisy vacuum tubes or poor selectivity, the published performance specifications have changed little since the 1940s and are still limited essentially to data on sensitivity and selectivity. Specifications on intermodulation distortion, cross modulation, desensitization and dynamic range, if they're mentioned at all, provide insufficient information for direct buyer comparison. Purchasing a new receiver under these conditions is a bit like buying a new car without knowing gas mileage or how many passengers it will carry.

The performance specifications for the high-frequency receiver shown in table 3 leave no question as to receiver performance and are recommended as a
Table 3. Specifications for a high-performance, high-frequency communications receiver provide a good format for amateur equipment manufacturers to follow. These specifications give complete reference and qualifying data and leave little question as to actual receiver performance.

Guides for receiver manufacturers to follow in the future. Well informed amateurs should demand nothing less.

References
A new look at the input stages of high-frequency communications receivers including some circuits for improving the IMD performance over that of any present amateur equipment.

Various efforts have been made in the past to build high-frequency communications receivers with wide dynamic range to combat the effects of cross-modulation and blocking. With the high level of galactic and man-made noise which is present up to about 30 MHz, receiver designers generally agree that a receiver with a 10 dB noise figure is more than adequate for high-frequency communications. This is equivalent to a sensitivity of 0.2 \( \mu \text{V} \) for 10 dB signal-plus-noise to noise (50-ohm input impedance, 2-kHz bandwidth). In most cases, on the high-frequency bands, the man-made noise which is picked up by the antenna is greater than 0.07 \( \mu \text{V} \), so the extraordinary sensitivity of a receiver with a noise figure lower than 10 dB is no great advantage. While this technique was initiated ten years ago by my company, Rohde & Schwarz, in Munich, amateur equipment designers have only recently started thinking along the same lines.

A noise figure of slightly less or equal to 10 dB can be readily achieved by using one of the new hot-carrier diode double-balanced mixers, such as the Minilabs SRA3H or SRA1H, which is
followed by a low-noise i-f amplifier ahead of a crystal filter. In practice this means that no rf amplifier stage is required. In vacuum-tube receivers one of the primary applications for the rf input stage was to provide agc but this can now be obtained (with negligible losses) with a PIN diode attenuator.\textsuperscript{1,2}

The first amateur equipment to use this new design technique is the Atlas 180 and its later models. There are some indications that this circuit is derived from the SouthCom SC130 Man-Pack Transceiver\textsuperscript{*} and the AN/PRC-104 of Hughes Aircraft, which both use the same technique. The main disadvantage of this rf input circuit is that it is practically impossible to suppress feedthrough energy from the oscillator to the antenna to 15 \(\mu\text{V}\) or less, a requirement of European regulatory agencies.

Some military and systems-oriented receivers still require noise figures of 6 dB or less because they are used with inefficient antennas (whip antennas with loading coils for marine, mobile or portable use, for example). Since it is difficult for the commercial communications equipment manufacturer to foresee whether the receiver will be used with a good antenna or a poor one, coupled with the requirement for low oscillator feedthrough, in many cases rf amplifier stages are still required.

Recently the German amateur journal, \textit{cq-DL}, published an extensive test report on the Atlas 180\textsuperscript{3} which showed fairly poor dynamic range with respect to what would be expected from a receiver with a double-balanced mixer input and high-power i-f stage before the crystal filter. As pointed out in a previous article,\textsuperscript{4} to obtain the specified performance every mixer must see a purely resistive load at both the i-f and image frequency. An analysis of the SouthCom and Atlas circuit reveals a tuned circuit between the double-balanced mixer and the i-f stage. Since the mixer is not properly terminated at the image frequencies, this results in a loss of at least 15 dBm for the mixer’s third-order intercept point, enhancing intermodulation distortion products.

mixer circuits

A recent survey published in Germany\textsuperscript{5} showed the results of a series of tests regarding the creation of unwanted spurious in double-balanced mixers as a function of termination. All tests were run with a high-level Minilabs SRA1H mixer which requires a local-oscillator input of 23 dBm (200 milliwatts). The results of these tests are listed in table 1.

Although the Minilabs SRA1H is capable of providing a third-order intercept point of 30 dBm, table 1 indicates

\textsuperscript{*}Atlas Radio is licensed by SouthCom International to use the circuits developed by SouthCom for military and commercial communications equipment. Editor.
that you can lose as much as 22 dB of dynamic range because the mixer is not properly terminated. Therefore, to obtain maximum performance, it is essential to build an input stage which has the required input impedance from dc be adjusted to set the dc bias so the input impedance is exactly 50 ohms. This circuit has been designed for optimum dynamic range regardless of oscillator feedthrough and does not show any input selectivity which must, of course, be

up to more than 100 MHz. This stage must also have an intercept point of 25 dBm (the double-balanced mixer has about 5 dB loss so the mixer output is 25 dBm at 30 dBm input).

Extensive tests with various crystal filters have been conducted in the past and it was found that the crystal filter's input and output must be terminated beyond its normal frequency range of operation. This is because crystal filters, such as the KVG XF9B, at frequencies not too far from the center frequency, exhibit impedances between 5 and 10 kilohms (see fig. 1). These resonant effects would significantly reduce the dynamic range of the preamplifier if the filter was not properly terminated.

The best solution to the problem of a high dynamic range preamplifier is a high current field-effect transistor, type CP643 (Teladyne Crystalonics), in the circuit of fig. 2 where the input resistors can added. In most cases input selectivity can be provided by a 1.6-MHz highpass filter and a 31-MHz lowpass filter, so the losses there do not have to be considered.

![fig. 1. Input impedance and phase angle of the 9-MHz KVG XF9B crystal filter when terminated in 560 ohms in parallel with 33 pF.](image)

![fig. 2. Input resistance of Crystalonics CP643 preamplifier can be adjusted to 50 ohms by proper setting of the 250-ohm potentiometer, R1. Current drain is 30 mA.](image)
The complete rf input circuit, showing the CP643 high dynamic range pre-amplifier, double-balanced mixer, 2N5109 oscillator injection amplifier and 3N200 i-f amplifier is shown in fig. 3. The injection amplifier accepts about 200 mV input voltage from the local oscillator and amplifies it to the required level for the double-balanced mixer. The grounded-gate CP643 has 14 dB gain and is matched to the input of the KVG XF9B crystal filter. The 3N200 i-f amplifier has enough gain and agc action for most receiver designs.

**push-pull rf amplifier with wide dynamic range**

In many wideband, high dynamic range applications such as antenna distribution amplifiers, input rf amplifiers are required which combine extremely low distortion with low noise figure. In the past both voltage and current feedback have been used to counteract voltage and current distortion. The disadvantage of these circuits is that a stable input impedance can be achieved only over a relatively narrow bandwidth.6

Recent research has resulted in a new wideband amplifier design2,7 which has extremely low VSWR at both input and output as well as low noise figure. The push-pull circuit, shown in fig. 4, uses push-pull circuit to obtain wide dynamic range shown in fig. 5. Transformers are trililar wound on Indiana General F625-9-TC9 toroid cores.
second-order intermodulation products can be suppressed nearly 40 dB (over a single stage) by the push-pull arrangement shown in fig. 4. Two linear vhf power transistors are used in the circuit, and depending upon the large-signal handling requirements, either the 2N5109 (RCA) or BFR95 (Amperex) may be used. Both of these devices have an $F_T$ of 1600 MHz.

This circuit provides about 11 dB gain and exhibits exceptional freedom from second- and third-order intermodulation products, as plotted in fig. 5. The third-order intercept point occurs at an input of about 22 dBm. Three types of feedback are used: current feedback through the unbypassed 6.8-ohm emitter resistor, voltage feedback through the unbypassed 330-ohm base-to-collector resistor, and transformer feedback through a third winding on the wideband transformer to stabilize the input and output impedance. A mathematical analysis of this circuit is presented for interested readers in the appendix.

**summary**

With very little effort the third-order intercept point of high-frequency receiver input stages can be increased far beyond the values of any commercial equipment now on the market. Table 2 shows the third-order intercept point of several popular receivers presently being used by amateurs.

From the diagram provided:

**Figure 5.** Performance of the push-pull rf amplifier shown in fig. 4. With an input of -27 dBm (two-tone signal, 20 mV each), gain is 12 dB, third-order distortion products are down 100 dB and second-order IMD is down 105 dB. Third-order intercept point occurs at an input of about 22 dBm.
Since voltage and current feedback may result in input and output impedances which may not suit the design requirements, a wideband toroidal transformer with a high-permeability core (such as Indiana General, F625-9-TC9) can be used to arbitrarily set these impedances. The schematic below shows an amplifier using a transformer with voltage and current feedback. The input voltage, $v_i$, input current, $i_i$, and input impedance, $Z_i$, are given by the following equations:

\[
\begin{align*}
v_i &= (k \cdot v_o) + v_b + v_e \\
\frac{i_i}{v_i} &= \frac{(v_b + Y_{11}) + v_b}{v_e} \\
Z_i &= \frac{(k \cdot v_o) + v_b + v_e}{(v_b + Y_{11}) + v_b}
\end{align*}
\]

So long as the operating frequency is well below $f_T$, emitter and collector current are the same. Therefore, the input impedance of the stage will be

\[Z_i = R_k \left( \frac{k + A}{l - A} \right)\]

where

\[A = \frac{R_E (R_k + R_L)}{(R_E + R_k) R_L}\]

and the required value for the voltage feedback resistor, $R_k$, is given by

\[R_k = Z_e \left( \frac{1 - A}{k + A} \right)\]

the amplification of the stage is given by

\[A = \frac{1}{k \left( 1 + \frac{1}{2kZ_e} \right)}\]

Since it is advantageous to have a 50-ohm input impedance, and the output impedance of the stage is approximately 150 ohms, the collector winding is split to build a 4:1 transformer. Under these conditions the input impedance, $Z_i$, output impedance, $Z_o$, and voltage gain, $A$, are given by

\[Z_i = (k \cdot R_k) + \frac{R_L}{2}\]

\[Z_o = \frac{R_E}{2k}\]

\[A = \frac{1}{k \left( 1 + \frac{R_E}{2kZ_L} \right)}\]

The constant $k$, which determines the turns ratio between the base and collector coil (1:7:7 in fig. 5), can only be an integer. To obtain optimum performance in many cases, therefore, one of the values may have to be a compromise. In the circuit of fig. 5 the output impedance was only 23 ohms so a 27 ohm resistor had to be placed in series to obtain the desired 50-ohm output impedance.

**capacitance meter**

Dear HR:

I have received a number of queries regarding the programmable unijunction transistor used in the capacitance meter described in the April, 1975, issue of ham radio. The full part number of this device, which is manufactured by Texas Instruments, is A7T6028 (because of space limitations, the package is labeled AT6028). The 2N6027, 2N6028 and 2N6118 are similar.

Although I have not tried the Motorola HEP S9001 programmable unijunction in the circuit, I have letters from K6MYA and WA3IFQ who say they had excellent results with this device. Another possibility is the package of programmable unijunctions available from Radio Shack (part number 276-119).

The two series-connected 0.005 μF capacitors in the circuit may be replaced by a single 0.0025 μF capacitor. This apparently has caused some confusion.

Courtenay Hall, WA5SNZ
Dallas, Texas

October 1975
solid-state communications receiver

A five-band amateur-band receiver which features an active balanced mixer front end for improved intermodulation performance

Radio amateurs in Italy live in a special purgatory. The American ham magazines show us the beautiful equipment which is available, but customs duties and air shipment add about 100 per cent to the list price. This is probably one reason why we have a larger percentage of homebrew equipment here in Italy.

My first solid-state receiver had been working fairly nicely, but I wanted something with a little better dynamic range, especially on 7 MHz as broadcast stations on this band are a little more bothersome here in Europe. A receiver with better cross modulation and blocking characteristics would help. The receiver described here seems to have achieved this objective, although I am an inveterate experimenter and will no doubt make a few changes. My friend Luciano, I5FLN, who duplicated my circuitry and packaged it very nicely, calls his copy the 5-Band DXCC receiver (see photo above). He has worked over 150 countries on 7-MHz ssb. My re-
The receiver isn’t as pretty — I was too impatient to hear the results!

The receiver uses a mixture of U.S. and Philips transistors which I accumulated, but I have suggested alternate types which are readily available in the States. Enterprising amateurs should have no trouble substituting equivalents from the myriad of types available. Performance characteristics of the receiver are listed in Table 1.

Circuit Description

A block diagram of the receiver is shown in Fig. 1. The signal at the antenna first goes through bandpass filters, one for each band. Each filter consists of three capacitively-coupled tuned circuits which use high-Q toroids to reduce losses and suppress out-of-band signals.

A balanced mixer following the filter insures that local oscillator noise is down some 30 dB. The vfo covers 5.0 to 5.5 MHz and effects the first conversion on 80 and 20 meters; for reception on 40, 15 and 10 meters the vfo is heterodyned with crystal oscillators for mixer injection.

The output of the balanced mixer is applied to a 9-MHz crystal filter, a KVG XF9E. This is an 8-pole filter with a 6-dB bandwidth of 2.4 kHz, a shape factor of 1.8 and stopband attenuation.

greater than 100 dB. A 9-MHz fet amplifier follows and a second fet mixer converts the 9-MHz signal to 455 kHz for application to a 2.7 kHz wide Collins mechanical filter. Crystal oscillators at 8545 and 9455 kHz provide sideband selection and are selected automatically with the bandswitch in accordance with current convention. A 455-kHz i-f amplifier, balanced diode detector, agc and an audio IC complete the picture. All circuitry derives power from an adjust-
able, regulated +12 volt power supply. Total current drain is about 375 mA.

construction

As indicated in the previous description, the receiver contains nothing new or startling. However, it is in the construction that careful attention to detail pays off. The receiver was built in modules, each module housed in a mixer are on four small boards grouped around the bandswitch. The 9-MHz amplifier is further isolated in its own smaller box (see fig. 3). Bandpass filters F1 and F2 are on one board, F3 and F4 are on a second board, F5 is on a third and the balanced mixer is on a fourth. The objective here was to realize the maximum attenuation capability of the filters.

fig. 3. Mixer module showing the input filters (left) and 9-MHz amplifier (separate enclosure at right). The balanced mixer is on the vertical board in the center.

177x145x49mm (7x5.7x2 inch) high aluminum box, a commercially available size. Subdivisions within the boxes contain the functional sections, each on a piece of one-sided copper fiberglass circuit board. This was done to facilitate system modification. Modular construction also contributes to greater freedom from spurious products. All power leads enter the modules through 1500-pF feedthrough capacitors. Signal interconnections are by phone jacks.

mixer module

The input filters and the balanced mixer module

Transformer T1 is trifilar wound with a single primary and two secondaries in series. Transistors Q1 and Q2 should be selected for equal drain current with the gate at zero volts. The small box with the 9-MHz amplifier is completely shielded and isolated with a bottom and top cover of tinned copper sheet and is fastened with epoxy to the larger aluminum box. Only thus was I able to realize the maximum attenuation capabilities of the KVG filter; the filter itself is mounted externally. The gain of Q3 is agc controlled. Note that the leads carrying band-change informa-
fig. 4. Circuit of the 455-kHz i-f module. The mechanical filter, FL1, is a Collins F455Z7. T1, T2 and T3 are miniature 455-kHz i-f transformers (see text). Module construction is shown in fig. 5.

455 kHz module

The 455-kHz amplifier is on a single board (see figs. 4 and 5). The Collins filter provides good isolation between input and output so no elaborate precautions are necessary. I mounted the transistors in sockets for easy substitution. The four diodes used in the product detector, CR4-CR7, are Phillips AAZ15 (1N270) selected for equal forward resistance. The BF175 transistors,
fig. 6. The 5.0-5.5 MHz vfo for the five-band receiver. L1 is 34 turns no. 24 (0.5mm) on an Amidon T50-6 toroid core. Vfo construction is shown in fig. 7.

Q3 and Q4, are rf types with gain which diminishes with increases in collector current. The Fairchild 2N4134 or HEP S0017 are good substitutes; these types may also be substituted for the BC209 and EC209. Note that transistor Q5, a BC154, is a pnp type; a HEP S0019 may be used instead.

Transformers T1, T2 and T3 are slug-tuned Siemens transformers — actually a bit large (25mm square) for this application. The J. W. Miller series 2031 i-f transformers only 0.5 inch square (12.5mm) might be more fitting if you have small fingers. The bfo may be crystal controlled if desired; its frequency, of course, will depend on the filter used in the receiver.

vfo module
The vfo is in a box which I strengthened by various methods to achieve mechanical rigidity (see figs. 6 and 7). The components are on a small fiberglass board except for the small 40 pF variable capacitor. The 68 pF NPO affords temperature compensation and the 20 pF trimmer sets the band center. A 5:1 planetary drive gives nice easy tuning. A digital readout would have been even nicer, but would use a lot more power. Toroid L1 is installed edge-wise on the board by its leads and a small dab of epoxy. 15FLN used a Drake vfo which makes an excellent substitution with less work.

vfo converter
The circuitry and construction of the vfo converter module are shown in figs. 8 and 9. The 5.0-5.0 MHz vfo signal at the vfo input goes directly to amplifiers Q5 and Q6 when the bandswitch is on 3.5 or 14 MHz. When applied to the balanced mixer the product is at 9 MHz. When applied to the balanced mixer the product is at 9 MHz. When the bandswitch is on 7, 21 or 28 MHz the vfo signal is mixed with the output of an fet crystal oscillator and filtered before being applied to Q5 and Q6. Two crystal oscillators at 28 and 28.5 MHz cover important segments of the 10-meter band. The filters suppress undesired products from the diode mixer, CR7-CR10. These diodes should

be carefully selected for equal (\( \pm 20 \) mV) voltage drop at varied values of current, say 0.75, 2, 10 and 20 mA. This is a must if you want oscillator attenuation of 30 to 40 dB.

The four fet oscillators are on one board and are energized by +12 volts from the bandswitch; diodes CR1-CR4 select the output. Drain coils L1, L2, L3 and L4 are wound on slug-tuned forms. The wideband trifilar transformers, T1 and T2, are on a second board with the diode mixer. The next board has the three filter pairs, L5-L6, L7-L8, and L9-L10. Each pair is inductively coupled by mounting the two coils about one diameter (9mm or 0.4 inch) apart. Input and output for the filters is via CR11 through CR17.

The fourth board has wideband amplifiers Q5 and Q6. The BFY63 transistor is a high-gain rf type which may be replaced by a HEP S0014.
design called for amplification from 5 to 39 MHz. I used as short leads as possible and ceramic capacitors. L11 is a small rf choke and consists of 20 turns or so on a 5mm (0.2 inch) ferrite rod. T3 is wide-band and trifilar wound.

audio and power

Fig. 10 shows the rest of the receiver and Fig. 11 the interconnecting diagram.

I did not bother enclosing the audio section or power supply. Since I am not a high-fidelity addict, I used an audio IC which gives adequate volume for earphones or speaker. The TAA621 IC provides about 1 watt output with a 12-volt supply; an HEP C6093C or MC1454G may be substituted. L1 is a 5mm (0.2 inch) ferrite rod with 20 turns number-18 (1mm) wire; it and the two capacitors inhibit rectification of strong out-of-band rf signals (L2 in the power supply is the same). I rewound an old transformer to give me about 12 volts and added a simple regulator. If you have a three-terminal voltage-regulator IC such as the MC7812, by all means use it.

alignment

After installation in their respective modules, I initially set most of my toroids with a grid dipper coupled with a one-turn loop, and a receiver for frequency accuracy. The job is simplified if you have a frequency counter. A slight loosening or tightening of the wire will bring the toroid to desired resonance. For a visual indication I used a vtvm with an rf probe. For the input filters I put the probe on the gate of Q1 and set the ±1 dB points of the filters as follows:

<table>
<thead>
<tr>
<th>Filter</th>
<th>Frequency</th>
</tr>
</thead>
<tbody>
<tr>
<td>FL1</td>
<td>3.5 - 3.8 MHz</td>
</tr>
<tr>
<td>FL2</td>
<td>7.0 - 7.3 MHz</td>
</tr>
<tr>
<td>FL3</td>
<td>13.9 - 14.5 MHz</td>
</tr>
<tr>
<td>FL4</td>
<td>21.0 - 21.5 MHz</td>
</tr>
<tr>
<td>FL5</td>
<td>28.0 - 29.5 MHz</td>
</tr>
</tbody>
</table>

For inductances L1, L2, L3, L4 and L5 (Fig. 8) I coupled the receiver to T1 and energized the respective oscillator. The probe on the hot side of T1 indicated about 0.5 volt for each oscillator as each coil was adjusted to resonance. Adjustment of the three filters is more easily done with vfo injection; alternately, a signal generator and rf voltmeter may be
used to set their -3 dB response as follows:

| L5-L6  | 16.0 - 16.3 MHz |
| L7-L8  | 30.0 - 30.5 MHz |
| L9-L10 | 37.0 - 38.0 MHz |

I used a calibrated receiver to set the center of the vfo excursion with the 20 pF trimmer; rf output was 0.6 volt. I connected the vfo to the converter input connector and temporarily installed receiver S+N/N at 10 dB. I then introduced two more signals to the antenna, 5 mV each, at 28.75 and 28.8 MHz. The receiver output remained at 10 dB, i.e., distortion products were 88 dB below the two interfering signals.

For the blocking check I used one signal generator as before, 0.28 µV (-117 dBm) on 28.7 MHz, then introduced a second generator and adjusted

fig. 11. Module interconnections. Relay K1 is a 12-volt dpdt relay.

a 47-ohm, ½ watt resistor across the output jack. With the rf probe at this point and the bandswitch set on 80/40 I measured about 2 volts. The filters and drain inductances may be touched up so that the output stays at about 2 volts at any setting of the bandswitch. After interconnecting the other modules I made final adjustment following normal receiver alignment procedures.

It might be interesting at this point to describe how I measured intermodulation and blocking. For the intermodulation check I set one signal generator for 0.2 µV on 28.7 MHz and measured its frequency 100 kHz above, and 100 kHz below 28.7 MHz. In each case I advanced the amplitude of this second generator until the output S/N ratio deteriorated; when the amplitude was advanced to 70 mV the S/N ratio decreased to 3 dB.

low-cost
1296-MHz preamplifier

Low-noise, high performance
1296-MHz stripline preamplifier uses new Motorola MRF-901 microwave transistor

A welcome side effect of the FCC's recent allocation of frequencies near 960-MHz to the Land Mobile Radio Service is the introduction by semiconductor manufacturers of low-cost, high quality active devices for the low end of the microwave spectrum. This technological revolution has proved to be a boon to amateur activity in the 1296-MHz band by bringing state-of-the-art components within the price range of microwave experimenters for the first time. This article presents construction details and performance data on a pair of preamplifiers for 1296 MHz which use the low-noise (under 2 dB), low-cost (under $10.00) Motorola MRF901 microwave transistor. Future developments will undoubtedly bring us a multitude of transistors offering superior performance and/or lower cost.

Numerous previous articles have covered the design and construction of high quality preamplifiers for the 1296-MHz amateur band. These amplifiers used outstanding transistors from a number of different manufacturers. Designed primarily for military and aerospace applications, this generation of microwave transistors is characterized by high reliability over a wide temperature range, hermetic construction featuring a ceramic case with gold-plated leads, and (without exception) a cost far beyond the financial resources of the average experimenter.

The new transistors developed for the 960-MHz Land Mobile Band, with plastic cases and tinned-copper leads, are admittedly less rugged than their military predecessors; storage temperature is not above 150°C, breakdown voltages are lower and derating curves are steeper. These devices are, after all, intended for commercial service. Their reliability is, however, wholly adequate for an extended life in intermittent amateur service, and their electrical performance at 1296 MHz compares favorably with that of earlier devices costing an order of magnitude more.

design trends

Early solid-state uhf preamplifiers designed for amateur use achieved input and output impedance matching...
through the use of pi networks composed of piston trimmer capacitors and slab inductors. This approach, typified by the designs of Katz\(^2\) and Vilardi,\(^2,3\) assured a proper impedance match regardless of the transistor characteristics because of the pi network's unique ability to "match anything to anything." Unfortunately, the pi network's very versatility made it difficult for the amateur who lacked the proper test equipment to know exactly when his amplifiers were tuned for optimum performance. Additionally, extensive tweaking of the input and output circuits made it possible to inadvertently adjust the amplifier into a condition of instability, with the resulting oscillations ultimately destroying the fragile transistor.

The microstripline designs of Donecker\(^4\) and others changed all that. All matching transformers and reactances were etched onto a printed-circuit board, with no tuning adjustments whatever, so there was no need to optimize an amplifier on expensive test equipment. This approach made it practically impossible to destroy a transistor by inadvertently mismatching it. On the other hand, the lack of tuning adjustments made it impossible to compensate for minute differences between components or printed-circuit boards. And, since a board was computer designed to the parameters of a particular transistor, the experimenter had little opportunity to modify the design so he could use a different, more readily available device. In fact, some attempts to substitute transistors on the same circuit board led to a net degradation of the system noise figure to that of a simple diode mixer.

I attempted to rectify these limitations in my preamplifier designs by incorporating "tweaking" capacitors into a printed microstripline design.\(^5\) By allowing one input and one output adjustment per stage, an amplifier is easily optimized, while lessening both the test equipment requirements and the likelihood of circuit instability. The same design approach is used in the preamplifiers presented here.

There is, however, one situation where the pi network matching technique still excels. For optimum system performance, it is necessary to match the input to the first preamplifier stage for optimum noise figure, not optimum gain. Optimum noise figure is achieved by deliberately and precisely mismatching the applicable input. Most rf transistor manufacturers publish curves or tables of complex impedances for pro-

![fig. 1. Noise figure vs operating frequency for the Motorola MRF-901 transistor.](image-url)

![fig. 2. Input reflection coefficient, \(S_{11}\) and output reflection coefficient, \(S_{22}\), vs frequency for the Motorola MRF-901.](image-url)
per input and output power match. Unfortunately, proper mismatch information for optimizing noise figure is seldom provided. Thus, it may be desirable to use a wide-range pi network at the input of the first preamplifier stage so that the source reflection coefficient at figure optimized amplifiers around this transistor, and performance has consistently measured 2.8 dB (with the preamplifier looking into a high-quality double-balanced mixer). The 0.7 dB discrepancy is due, of course, to the familiar second-stage noise contribution,

![Schematic of the 1296-MHz preamplifier](image)

which noise figure is minimum can be empirically achieved.

**transistor characteristics**

Fig. 1 shows the manufacturer's claimed noise figure as a function of operating frequency for the MRF-901 transistor. At 1296 MHz the device is capable of delivering a noise figure below 2.1 dB. I have built several noise-

which was summarized quite well in the appendices to Reisert's recent article on 432 MHz preamplifiers. Working through the textbook formula, it is found that the noise-figure optimized MRF-901 stage's intrinsic noise figure is on the order of 2.3 dB. Thus, the losses and mismatch errors inherent in this design still yield performance within 0.2 dB of optimum.
The specification sheets for the MRF-901 list input and output reflection coefficients ($S_{11}$ and $S_{22}$) in polar form, tabulated for numerous combinations of frequency, power supply voltage and quiescent collector current. The two static conditions of greatest interest to the amateur are 10 volts at 5 mA (for a noise-matched first amplifier stage), and 10 volts at 10 mA (for a gain-optimized second preamplifier stage), as discussed in a previous article.\(^5\) Reflection coefficients corresponding to these bias conditions were plotted on a Smith chart, then connected with a smooth curve as shown in fig. 2. The design parameters for the 1296 MHz preamplifiers were determined from interpolation of this Smith chart data.

**design procedure**

Two preamplifier stages are discussed here, one optimized for noise figure, the other for power gain. The gain-matched second stage was designed along lines analogous to that described in my previous articles. No noise-matched reflection coefficients were available from Motorola for the MRF-901, so a pi network was included in the input to the noise-figure matched stage, as discussed previously.

Fig. 3 is a functional schematic of the 1296-MHz preamplifier stages (the only differences between the stages optimized for noise figure and gain are the quiescent collector current [5 and 10 mA, respectively], and the use of an additional input matching capacitor, $C_3$, in the noise-matched stage).

The system noise figures of several gain-matched 1296-MHz preamplifiers I've built with MRF-901 transistors all measured between 3.2 and 3.5 dB, while yielding 12 to 14 dB of power gain. Thus, for all but the most critical applications, the use of a noise-figure matched first preamplifier stage may not be necessary (see fig. 4).

**construction**

Fig. 5 is a full-sized printed-circuit layout for either preamplifier stage. The only visible difference between the gain-

---

**fig. 4.** Typical power gain and noise figure of the 1296-MHz preamplifier as a function of collector current.

**fig. 5.** Full-sized printed-circuit board for the 1296-MHz preamplifiers using MRF-901 transistors. Component layout is shown in fig. 3.
matched and noise-matched stages is the incorporation of a variable capacitor, C3, in the noise-matched stage. Note, however, that the quiescent collector current differs between the two stages. More on this later.

The amplifiers are built on 1/16 inch (1.5mm) G-10 fiberglass-epoxy circuit board, double-clad with 1 ounce copper.

I still receive occasional letters from readers who question my repeated use of glass-epoxy material at 1296 MHz. I will concede that the 0.2 dB excess noise figure above optimum which I have mentioned previously may be due to losses in the substrate. However, I feel that 0.2 dB is a small price to pay for the convenience and ready availability of this low-cost printed-circuit material.

Construction of these amplifiers is substantially the same as that of my previously published circuits. If you are unfamiliar with the fabrication of microstripline amplifiers, you are urged to refer to reference 5 for specific construction hints, as well as suggestions for tuneup and operation. That material is not repeated here.

bias circuit

The zener bias circuit introduced by Reisert6 is not only simpler but also electrically superior to the active bias scheme I used in some of my earlier designs. Reisert’s circuit is presented in fig. 6 along with component values for the two required bias conditions. I refer the interested reader to his very fine article for a complete description of the operation of this bias circuit.

One appealing feature of this biasing scheme is that the power supply voltage can be varied upward or downward, as required, to optimize the stage for gain or noise figure. In this manner the performance of the preamplifier can be readily tailored to the requirements of the system in which it is installed.

conclusion

As the commercial microwave communications industry expands, sophisticated amplifiers have come within the reach of the average amateur experimenter. For those who prefer not to build their own equipment, low-cost 1296-MHz preamplifier modules are now available. A commercial version of the gain-matched stage, featuring a guaranteed maximum noise figure of 3.2 dB is currently available for under $40 from Microcomm.*

Most modern communications receivers for the 28-30 MHz range are designed with dynamic range as the primary goal. Low noise figures generally require more gain ahead of the mixer and hence decrease the dynamic range. Furthermore, noise figures below 10 dB are seldom usable at these frequencies because the local ambient noise usually is the limiting factor for weak-signal detection.

Satellite reception and vhf/uhf converters usually require lower noise figures than the typical communications receiver will provide. Therefore, for these applications it's necessary to install a low-noise preamplifier ahead of the receiver. A suitable preamp which is inexpensive and easy to build is described in this article. It has proven to be a workhorse for many Oscar 6 and 7 operators and has also been used as a low-noise i-f preamp for use with vhf and uhf converters.

Many of the requirements for low-noise preamplifier design were discussed in an earlier article and will not be reiterated here. Field-effect transistors were the prime candidates for this application because they are inexpensive, readily available, and yield low intermodulation distortion.

**circuit discussion**

The three preamplifier configurations shown in fig. 1 were evaluated to determine which was the most suitable for low-noise operation at 28-30 MHz. Models of each were built and tested. The grounded-source circuit (fig. 1A) was discarded since it required neutralization for unconditional stability. Loading the drain circuit helped, but gain had to be reduced considerably before complete stability was obtained.

Next, the grounded-gate circuit (fig. 1B) was tried. Although it was stable, gain was lower than expected and the noise figure was slightly higher than the grounded-source configuration. The cascode circuit (fig. 1C) seemed to fill the bill; low noise, high gain and stability...
were easily obtained using two single jfets or a dual-gate mosfet.

Noise figures of 1.5 to 2.0 dB were relatively easy to obtain with this circuit. The optimum source (input) impedance is 2 to 4000 ohms. After calculating the unloaded and loaded Q of such circuits (fig. 2A), I concluded that the noise figure was limited by input circuit losses, not device limitations. I tried the L-network input circuit (fig. 2B) and was pleasantly surprised by the results. The circuit losses were definitely lower. An rf choke which is parallel resonant at the operating frequency was used in the final configuration shown in fig. 2C. This method of matching is one of the secrets to the low noise figure of this preamplifier.

device selection

The original circuit (fig. 1A) used a jfet. The Siliconix E300 and popular 2N4416 transistors worked equally well. These devices also worked well in the cascode circuit (fig. 1C). The Fairchild FT0601, a dual-gate mosfet, worked as well in the cascode circuit as the E300 types. Typical noise figures of 1.25 to 1.75 dB were easily obtained but the real surprise came when the inexpensive, diode-protected, dual-gate RCA 40673 mosfet was tried in the circuit. It consistently yielded lower noise figures than any of the other devices I tested: typical measured noise figures were less than 1.0 dB.

circuit description

The original preamplifier circuit had limited publication in March, 1972, and was revised a year later. A complete schematic of the latest version is shown in fig. 3. The input network is as described earlier. RFC1 is parallel resonant at 28-30 MHz; values of 15 and 30 microhenries should be usable with little degradation. Inductors L1 and L2 are low-loss toroidal coils wound on Amidon cores, are small, and provide high
Q. Hence there is very little mutual coupling between the input and output circuits. Capacitor C1 allows optimization of noise figure and usually can simply be peaked for maximum gain. Capacitor C2 tunes the output circuit to the desired operating frequency. The circuit values shown in the schematic will permit operation from about 25 to 35 MHz without any component changes.

Attention is called to the use of a ferrite bead on the gate 2 lead to the mosfet, Q1. Careful testing revealed that most dual-gate mosfets tend to oscillate at uhf, typically at 750 to 900 MHz. This can be readily observed on a uhf spectrum analyzer. The reason for this is easily understood when you consider that there is a small, finite inductance present between gate 2 of the semiconductor dice and the outside of the transistor package. All attempts to bypass this lead were unsuccessful. The ferrite bead, however, did the trick since it essentially puts a lossy element on the lead and suppresses the uhf oscillation.

This same oscillation effect has also been observed on other dual-gate mosfet preamplifiers operating at frequencies as high as 500 MHz. In all cases a ferrite bead on the gate lead solved the problem.

Resistor R2 can be added to the circuit, if desired, to increase bandwidth with a small sacrifice in overall gain. Diode CR1 is an idiot diode which prevents damage to the mosfet if the power supply polarity is accidently reversed.

construction

Construction of the 28-30 MHz low-noise preamp is very straightforward and is similar to that used for the low-noise uhf preamp described in reference 1. A small section of double-sided printed-circuit board is attached to the cover of a small aluminum box (such as the Pomona 2417). BNC connectors are used for the input and output. The use of toroidal inductors eliminates the need for any shield if the input and output inductors are located at opposite ends of the box and are oriented at right angles to one another. Further construction details are shown in the photograph.

Although the RCA 40673 is a diode-protected mosfet, care should be exercised when handling the device to prevent any possible damage from static electricity. The best procedure is to first grasp the device by the case and then pick up the circuit board. With this technique the potentials are equal and the mosfet leads can be safely soldered into the circuit.

Any low-loss trimmer capacitors may be substituted for C1 and C2. The miniature JFD units I chose were based on
the small size needed to package the circuit in the Pomona 2417 enclosure.

**operation and test**

For final checkout the input to the preamp should be terminated with a 50-ohm resistor, a noise generator or a 28-30 MHz antenna. The output can be connected to a receiver or i-f amplifier.

---

**fig. 3. Low-noise 28-30 MHz preamplifier which provides 20 to 25 dB gain and typical noise figure of 1.0 dB uses a dual-gate mosfet in the cascode circuit.**

C1 20 pF trimmer (JFD DVJ300 or equivalent ceramic trimmer)

C2 50 pF trimmer (JFD DVJ305 or equivalent ceramic trimmer)

FB Ferrite bead (56-590/65/3B or equivalent)

L1 25 turns no. 24 (0.5mm) on Amidon T50-10 toroid core

L2 22 turns no. 24 (0.5mm) on Amidon T50-10 toroid core, tapped 7 turns from cold end

R1 150 ohms typical (see text)

R2 2000 ohms typical (see text)

---

The current drawn from the 12-volt power supply should be checked for proper operation: 3.0 to 7.0 mA is fine. If the current is too low or too high the value of R1 should be raised or lowered accordingly.

The only adjustments are to peak the input and output capacitors (C1 and C2, respectively) for maximum output. If a noise generator is available, C1 can be adjusted for lowest noise figure. However, as noted previously, in most cases good low-noise performance can be obtained simply by adjusting C1 for maximum gain.

---

The extremely low cost of this unit makes it a real bargain. Once you have one in operation, you’ll wonder how you ever did without it.

Special thanks go to all those who have duplicated this preamp and encouraged me to write this article. I hope its use will improve your station’s performance.

bfo multiplexer
for a multimode detector

Cmos logic oscillator deck and phase-locked loop are combined for a multimode detection system.

demodulated if the NE561 is used as a combination product detector and phase-locked loop discriminator.

Construction details are provided for a 455-kHz multimode detection system using the NE561. The IC module is packaged inside the original bfo coil’s shield can for ease of installation. It is most economical, considering the features it provides, since surplus FT-241A crystals may be used and the ICs are not expensive.

Cmos logic oscillators

Crystal-controlled oscillators using linearly biased cmos logic elements are described in RCA’s applications literature. In the basic circuit, shown in fig. 1, R1 biases the logic element as an inverting linear amplifier. The pi-type feedback network provides 180 degrees phase shift at the crystal’s parallel resonant frequency to produce oscillation. The crystal sees a load capacitance equal to the series equivalent of C_s and C_t.

With regards to stability, the cmos oscillator circuit shown here is competitive with good discrete component de-

For several years I’ve been experimenting with solid-state circuits to replace various receiver subsystems at my station. Most of the stages of my venerable HRO-50T have been rejuvenated in this fashion. Installation of this multimode detection system was a major step toward providing the performance and operating conveniences demanded of today’s best receivers.

In the bfo multiplexer a single IC functions as an upper-sideband crystal oscillator, lower-sideband crystal oscillator, tunable bfo for CW, or as a limiter of the i-f signal for fm or synchronous a-m reception. The desired oscillator (or the limiter) is gated on by grounding its digital control line. Multimode reception results when the multiplexed output of the oscillators and limiter is applied to a product detector. Fm signals can also be

fig. 1. Basic crystal oscillator circuit using a cmos inverter or gate. Crystal Y1 is 10 MHz or less.
signs. The prototype of a 3.3 MHz oscillator that I am using in an industrial application, for example, is built around a high quality crystal and drifted less than 20 Hz between 0°C and 70°C without any temperature compensation. Power supply sensitivity has been reported as 3.5 ppm for a 25 per cent change in supply voltage. Power drain, although proportional to frequency, is extremely low and a wide range of supply voltages can be accommodated.

Resistor R2 in fig. 1 is the only component whose design value must change with frequency. At high frequencies it must be reduced or eliminated since the attenuation and phase shift it introduces increases with frequency.

**multiplexer circuit**

The idea which gave birth to the bfo multiplexer was that of obtaining four amplifier-oscillators, each with an on-off control, from a single quad 2-input NOR gate package and combining their outputs in a resistive summing network. The resulting circuit is shown in fig. 2. The supply voltage, $V_{DD}$ should be between 3 volts and 15 volts. Regulation is necessary only to avoid exceeding the 15-volt upper limit. With a 9-volt power supply and the component values shown, a 770 mV p-p square wave output was observed. If you must use different summing network component values, use about 1000 ohms per volt of the supply in series with each output of the CD4001 IC to avoid overloading it.

Transformer T1 in the tunable oscillator circuit is a Radio Shack transistor oscillator coil. However, any high-Q coil-capacitor combination which resonates at the i-f will do. The stability of this circuit, particularly warm up drift, was noticeably better than that of the original circuit.

The input from the i-f amplifier should be at as high a level as possible for good limiting. This consideration should present no problem since the high input impedance of the CD4001

will not load a high-Q tuned circuit. Sensitivity for full output is about 300 mV p-p. The input level is adequate if a rounded square wave is obtained at the output with an a-m signal tuned in.

**detector circuit**

The bfo multiplexer provides a-m detection capability for a receiver equip-
ped with only a product detector while simplifying mode switching. In this application it replaces the original bfo. I first used the bfo multiplexer with a MC1496G product detector. The results were excellent. Gain and dynamic range of this device exceed that of the NE561. A further advantage was that both the detector and bfo could use the same supply voltage. On the other hand, the gain and dynamic range were not needed and fm detection capability was desired.

When used with the NE561, a 90 degree phase shift network is required in series with the output of the bfo multiplexer as shown in fig. 3. During a-m reception the network compensates for the fact that the NE561 locks up in quadrature with the signal at its phase detector's input.

The i-f input level to the NE561 should be held to about 100 mV rms for minimum distortion. If this is done the audio output level will be at least half that for narrow-band fm, about the same for ssb and CW, and at least twice for a-m if both sidebands are passed by the i-f filters. Note that the fm audio output level is proportional to the percentage deviation and cannot be increased by increasing the signal level. The two 0.004 μF capacitors limit the audio bandwidth to about 4 kHz.

The vco output of the NE561 is a 0.6 volt p-p square wave at the a-m carrier or bfo frequency. It appears to be ideal for use as an input to a digital dial adapter for accurate received frequency measurement.

**construction**

The multimode detection system was built on three 2-1/2 × 1-3/4 inch (57×45mm) copper-clad epoxy boards. The boards were stacked with phenolic posts, then slid inside the original bfo coil's shield can. The top board was bolted to the top of the shield can. Since the boards fit snugly inside the can, the complete assembly meets mechanical stability requirements. There is still room in the shield can for a fourth board containing a cable connector, if you are so inclined.

The crystals and associated components are mounted in an octal socket on the top board. The oscillator coil and its associated components are mounted nearby. The top of the can is cut out to allow access to the crystals and the coil's adjustment screw without disassembly. Space could have been found for two trimmer capacitors for the crystal oscillators, had this been considered necessary.

![Closeup view of the detector board, right, and the first multiplexer.](image)

**fig. 3. Phase-locked loop detector circuit for use with the bfo multiplexer.**

Switch S1B is ganged with the bfo multiplexer mode switch, S1A, in fig. 2.
The CD4001AE is mounted in a 14-pin DIP socket on the middle board. The two rows of resistors which flank the socket in the photograph are the pull-up resistors, summing resistors, and 22M feedback resistors. The pads were made with a Vector pad cutting tool.

The layout of the detector board can also be seen in the photograph. The fine-tuning control is adjacent to pin 16 of the IC. With the bfo multiplexer installed in the receiver, it can be reached through a hole drilled in the chassis. Alignment consists of setting the free-running frequency of the NE561 (bfo multiplexer off or disconnected) to within 200 Hz of 455 kHz using this control.

**operation**

This detector system may be operated just like any other product detector-bfo combination. Most of the time you will be completely oblivious to the fact that there is a phase-locked oscillator in the system. However, when the limited i-f signal is applied to the NE561, several peculiarities may become evident. If conditions are just right, a coded CW signal may be demodulated in the a-m position as a series of chirps as the vco falls into and out of lock on each dit or dah. Another anomaly results when an interfering heterodyne is coincident with one of the voice sidebands of an a-m signal. Depending on their relative strengths, the loop may lock up on the interference, rather than the a-m carrier.

Excessive lock range can also be a problem. If strong signals hold the vco until you have tuned well past them, seemingly putting hysteresis in the tuning mechanism, a circuit modification may be in order. I found that a 22k resistor between pin 7 of the NE561 and its power supply reduced the lock range to ±6 kHz. A less drastic solution is to switch to the CW oscillator those few times it is necessary to bring the vco back on frequency.

These phenomenon are simply quirks and are not reasons for not taking advantage of phase-locked loops for multimode detection applications. Other types of detectors have other problems under the same conditions.

160-10AT SUPERTUNER™
Want an antenna tuner to match everything between 160 and 10 through balanced line, coax line and random line, pump out the full legal limit and look and sound good doing it? Supertuner™ is the one for you at just $119.50

160-10AT-3K SUPER SUPERTUNER™
Designed and engineered to be compatible with the full-power highly efficient modern amplifiers now available to the amateur. In our opinion the finest tuner on the market today. $229.50

80-10AT SKYMATCHER™
Here's an antenna tuner for 80 though 10 meters, handles full legal power and matches your 52 ohm transceiver to a random wire antenna. 80-10AT is yours for only $59.50

160AT SKYMATCHER™
160 meters is a blast! This antenna tuner brings the fun of 160 to you while handling full legal power. Matches your 52 ohm transceiver to your present antenna or any random length antenna ranging from a short whip to an extra long wire. Only $59.50

160XV TOP BANDER™
160 meters is only a step away from 80 with this remarkable Dentron 160 meter transverter. Specifically designed to bring simple low cost 160 meter capability to any amateur station currently equipped for 80 meter CW, SSB, or AM operation. No modification of your existing equipment is required. Just "plug in and play" and you're on 160 meters with 100 watts transmit power and a super sensitive receiver. Just $199.50 $229.50

COMING ATTRACTIONS FROM DENTRON
- 160 meter solid state receiving converter
- "Dual-meter" in line wattmeter
- Audio Rectification Filters for RFI problems in HiFi, tape recorders, organs, intercoms, etc.
Write for full details

56 october 1975
SKYMASTER™
A fully developed and tested 27 foot vertical antenna covers entire 10, 15, 20, and 40 meter bands using only one cleverly applied wave trap. A full ¼ wave antenna on 20 meters. Constructed of heavy seamless aluminum with a factory tuned and sealed HQ Trap, SKYMASTER™ is weatherproof and withstands winds up to 80 mph. Handles 2 KW power level and is for ground, roof or tower mounting. Radials included in our low price of $84.50

SKYCLAW™
A tunable monoband high performance vertical antenna, designed for 40, 80, 160 meter operation. SKYCLAW™ gives you the following spectrum coverage:

<table>
<thead>
<tr>
<th>BAND</th>
<th>BANDWIDTH (kHz)</th>
</tr>
</thead>
<tbody>
<tr>
<td>160</td>
<td>50</td>
</tr>
<tr>
<td>80</td>
<td>200</td>
</tr>
<tr>
<td>40</td>
<td>entire band</td>
</tr>
</tbody>
</table>

Tuning is easy and reliable. Rugged construction assures that this self-supporting unit is weatherproof and survives nicely in 100 mph winds. Handles full legal power limit. All this coverage for $79.50

160 METER MOBILE TOP BANDER™
Now you can operate on 160 meters in your car, boat, plane or RV. Covers 10 kHz bandwidth without adjustment and entire 160 meter band with adjustment. It’s streamlined 10½ ft. length includes a slim lightweight, factory sealed loading coil. Handles 500 watts. Standard ¾”-24 ball mount thread. Now $59.50

ALL BAND DOUBLET
This All Band Doublet or Inverted Type Antenna covers 160 through 10 meters. Has total length of 130 feet (14 ga. stranded copper) although it may be made shorter if necessary. This tuned Doublet is center fed through 100 feet of 450 ohm open balanced transmission line. The assembly is complete. Add rope to the ends and pull up into position. Tune with the Dentron Super Tuner and you’re on 10 through 160 meters with one antenna! Now just $24.50 for the Dentron All Band Doublet.

NOTE: All prices are postpaid in U.S.A.

More Details? CHECK-OFF Page 110
In a previous article about a 1296 MHz balanced mixer\textsuperscript{1} I mentioned using a similar circuit for 2304 MHz. This elicited several requests for information about the 2304 MHz mixer shown in fig. 1. However, since I felt that the ceramic board construction was beyond the facilities available to most amateurs, I was unable to respond. Since I was curious to see if simple construction techniques would still work at 2304 MHz, I finally made the version shown in fig. 2 which uses an ordinary printed-circuit board. To my surprise, the second version exhibits better performance than the “professional” one.

The basic design, shown schematically in fig. 3, is identical to the 1296 MHz mixer described in QST and consists of a 3 dB quadrature-hybrid coupler, quarter-wave stubs for bypassing, and a low-Q pi network for i-f impedance matching. The major difference is the use of 1/32 inch (0.8mm) double-clad, G10 epoxy-fiberglass circuit board, rather than 1/16 inch (1.5mm), to maintain a reasonable aspect ratio. The line dimensions shown in fig. 4, however, are more critical because of the thinner board and higher frequency.

I cut the printed-circuit mask directly to size on Rubylith* with a knife and a ruler so it should be possible to
duplicate the layout with tape or by cutting the pattern directly into the copper and peeling away the excess. Dimensions A through E, and especially line widths A and B, should be within 0.005 inch (0.1mm) of the values shown for best results.

**construction**

Construction is exceedingly simple, requiring only a drill and a vise. The circuit board is attached to a shelf in a 2-3/4 x 2-1/8 x 1-5/8 inch (70x54x41mm) Minibox. The shelf dimensions are shown in fig. 5. Use enough screws to keep the board flat against the shelf and to provide a ground path for capacitor C4. Metal screws have no effect if they are kept away from the microstrip transmission lines. Approximate placement of the screws can be seen in fig. 2.

Critical parts are the blocking capacitors, C1 and C2, the connectors, and, of course, the mixer diodes. The blocking capacitors should be low-loss chip capacitors, preferably physically small to maintain a low VSWR. The same considerations, loss and VSWR, also apply to the connectors; SMA type connectors similar to the ones shown are available very reasonably from E. F. Johnson.

**adjustment**

Adjustment is the height of simplicity. A two-meter converter is connected to the i-f output, and a clean 1 to 2 milliwatts at 2160 MHz is fed into the LO connector. Apply about 1.5 mA of bias current to the diodes and apply a

---

moderately strong signal at 2304 MHz. When the bias current and i-f trimmer capacitor are adjusted for maximum signal, the tune-up is completed.

performance

A testimonial to the performance of this mixer is that, at the Eastern VHF/UHF Conference earlier this year, the original version won a certificate for the lowest noise-figure 2304 MHz converter. The measured noise figure was 7.1 dB (i-f noise figure, 2 dB), but, in the interest of fairness, W1JAA insisted that 3 dB be added because of the poor image rejection, so the final noise figure was 10.1 dB. The new version described in this article measures 2 dB better! The mixer has a conversion loss of 6.1 dB.

Noise figure, both theoretical and measured, is the sum of conversion loss plus i-f noise figure. With a 1 dB noise figure at two meters, an overall noise figure of approximately 7 dB could be realized. This should compare favorably with most other mixers at this frequency; W2CQH's interdigital mixer$^2$ may be better, but it is also more complex. Isolation between the local-oscillator to the rf ports measures 22 dB; this indicates that the hybrid coupler is working properly and that the diodes are well matched to 50 ohms (any power reflected from the diodes will decrease the isolation).

dc bias

A few words about the value of dc bias in mixers may be in order. I have not seen any other amateur designs which include biasing of the mixer diodes, whereas it is fairly common practice in commercial mixers. Prior to building my first balanced mixer (for 1296 MHz), I made some measurements of diode impedance versus rf signal power (LO) and bias current. The conclusion was that, with dc bias, less
LO power is required to raise the diode impedance to 50 ohms, and the impedance is less sensitive to the drive level. We are, in essence, substituting readily available dc power for hard-to-get rf power! This is borne out by the fact that my mixers work fine at LO levels of one milliwatt, while other, similar designs\textsuperscript{3,4} specify around three milliwatts. Also, Tilton recently mentioned\textsuperscript{5} several balanced mixers which were rejected by \textit{QST} — their poor performance was apparently due to lack of LO power. Addition of dc bias might have helped significantly.

Bias current is not critical (in this mixer minimum conversion loss was achieved with 1.8 mA of diode current), but it can be varied from 1.0 to 2.6 mA with only a 1 dB increase in loss. With no bias, however, conversion loss increased to 13 dB. Small changes in LO power, simulating normal drift, also had a minimal effect.

One final advantage of dc biasing may be to force the diodes to operate at the same current, and hence at similar impedance, for no attempt at diode matching or individual tuning was made in order to achieve the stated performance.

\textbf{balanced-mixer design}

I have received several queries about designs for other frequencies. These can be made by direct scaling from this design or the 1296 MHz version, following these guidelines:

1. Dimension A is for a characteristic impedance, $Z_0 = 50$ ohms, and B for $Z_0 = 35$ ohms. No change is required if the same board material is used.

2. Dimensions C and D are one-quarter wavelength long at a frequency halfway between the signal and LO frequencies (2232 MHz in this case).

3. Dimension F is one-quarter wavelength long at the signal frequency (2304 MHz).

4. Dimension G is one-quarter wavelength long at the local-oscillator frequency (2160 MHz).

5. Wavelength in microstrip line is a function of $Z_0$, so use a graph of $Z_0$ and $\lambda m$ if you change board material (different dielectric constant).

6. Dimension E is D minus A.
7. Use a low Q i-f circuit which matches the impedance of the diodes (100 to 200 ohms at the i-f).

If the same board material is used (1/32 inch G10) scaling dimensions C, D,

Fig. 4. Full-size printed-circuit board for the 2304-MHz balanced mixer. Microstrip dimensions shown at right may be scaled to other frequencies (see text).

F and G directly by the ratio of the frequencies will work fine. As mentioned above, good isolation from the LO to rf ports is an indication that everything is working properly; measure this after all other adjustments have been made.

Fig. 5. Shelf dimensions for installing the balanced mixer in a standard Bud CU-3000A Minibox.

**conclusion**

The balanced mixer will provide excellent performance which is easily duplicated and maintained. Use of a low-loss filter at the input is recommended to improve image rejection; there are no other responses if a clean local-oscillator signal is used. A preamplifier may be used for even lower noise figure, and the mixer will provide a low vswr load for the preamp to help stability. However, unless you really need the small (and costly) improvement a preamp provides, the mixer alone has two major advantages — it is much harder to burn out, and it will not oscillate.

Adding satellite receivers to your repeater won't bring in OSCAR 7 — but it might improve your terrestrial coverage.

Many users of low-powered handie-talkies have found that the theory of reciprocity proves to limit their ability to communicate through a repeater. Reciprocity implies that, with equal receiver sensitivity and antenna gain on both ends of a path, equal transmitter power is necessary for both stations to hear each other with the same signal strength.

Generally, a repeater's transmitter will have a 17 to 23 dB power advantage over a two-watt portable, effectively reducing the repeater's usable sensitivity by the same amount. This is the typical case of hearing the repeater full quieting but not being able to access it, even though the repeater's receiver is very sensitive.

Assuming that it is desired to retain the present transmitter coverage, there are several ways to balance out the transmit-receive range. In the case of a split-site system, the existing receiver can be relocated at the highest elevation possible. This is, of course, assuming that the repeater was set up initially with equal transmitter and receiver.

Fred Studenberg, Jr., W4YAK*

*Electronics Communications, Inc., St. Petersburg, Florida 33710
heights. Many repeaters were originally designed for use with mobiles that ran 30 to 60 watts and tended to hear as well as they transmitted to the repeater.

**satellite receivers**

If you operate a single-site system, or have run out of tall buildings and towers, there is another solution to the problem. The concept of satellite receivers has been applied successfully for some years by commercial users and some advanced repeater groups. These remote receivers, located in areas away from the main receiver, relay the weaker incoming signals by vhf or uhf links to the main transmitter.

Ideally, a satellite receiver system should have circuitry that will automatically select the audio from the receiver that is hearing the best quieting signal. However, our repeater group has found that very elaborate methods are not really needed. A typical fm receiver will yield usable audio from any signal that can open the squelch, even though the receiver may only be quieted by 10 or 15 dB. With this in mind, a four-

![Diagram](image)

**fig. 1.** Satellite receivers expand the two-way coverage area of repeater WR4ALT in Tampa, Florida.

channel scanner receiver was built for the 450-MHz band. **Fig. 1** shows how this is used in our satellite system.

The receiver will lock up on the first link transmitter it hears during the scan process. The system tends to seek out the link transmitter that is carrying the best signal, since a link carrying a "chopping" mobile signal will also be "chopping" into the link receiver. The scanner link receiver will tend to unlock and lock up on a solidly keyed link.
from a receiver that is hearing a full quieting signal. To avoid wear on the link transmitter's keying relay and also to provide security to the link receiver, the actual presence of a signal is indicated by a 10-kHz subcarrier modulated on the link transmitter. The squelch, and consequently the scanning action, is dependent upon the presence of the 10-kHz subcarrier.

To satisfy FCC requirements, each satellite system is licensed as an auxiliary link station, and the link transmitters are identified continuously by a 4-kHz MCW signal. This is filtered out in the link receiver, and the main transmitter is identified by its normal identification circuits. Regulations require control of the link transmitter. In our case, a common radio control frequency is used for all five sites, simplifying the control operator's equipment requirements. Link frequencies in the 450-MHz band were chosen since monitoring of the link transmitters is not required. Link operation on 220 MHz would require four-frequency monitoring capability.

Selection of the remote sites should be dictated by "dead spots" in the repeater's current coverage area. Naturally, high antenna heights are desirable, but even low antenna satellite receivers will do wonders for filling in receive coverage for the handie-talkie users.

Referring to fig. 2, the satellite receiver's COR keys the 10-kHz oscillator and also the link transmitter, but through a three-second hold-in timer. This effectively eliminates the squelch tail from the link receiver since it resumes scanning when the subcarrier is removed, even though the carrier is still present. A 10-kHz tone was chosen to allow fast detection time. A Signetics NE567 phase-locked loop tone decoder is used, and it can recognize the subcarrier in less than 1 millisecond. A scan search rate of 25 milliseconds per channel is used, allowing a worse case delay of about 80 milliseconds when selecting different satellite receivers. This has proven to be a very acceptable method of voting without any of the problems encountered when trying to make one-to-one comparisons in strengths of the remote receivers.
High-performance crystal discriminator for vhf fm

Many amateurs, and professional design engineers as well, have attempted to design single-conversion fm receivers only to scrap their brainchild because of low recovered audio and the resulting noisy audio output with poor squelch action. A single-conversion vhf fm receiver must have an intermediate frequency of 5 MHz or higher to provide adequate image rejection. The percentage of deviation is quite small at the higher intermediate frequencies so ICs utilizing quadrature detection may provide less than a millivolt of recovered audio. A simple solution to this problem is to increase the Q of the quadrature coil or use a crystal in its place. Unfortunately, however, these ICs become very unstable and impossible to tame when the Q of the quadrature resonator is increased.

crystal discriminators

Most of the novel discriminator circuits, such as the pulse-counting or digital type and transformerless type, as well as the conventional Foster-Sealey, Round-Travis and the ratio detector, do not provide enough recovered audio to be useful at the higher i-f frequencies. Crystal discriminators are quite popular in some of the more sophisticated commercial radios. In fact, Motorola uses a two-crystal discriminator to obtain a plus and minus voltage swing for automatic frequency control in some radios. The crystal discriminator was mentioned briefly in QST but no specific values were given.¹

Most crystal filter manufacturers market a crystal discriminator which
complements their crystal filter line so they are very reluctant to disclose the internal workings of these devices. However, several hours of investigation turned up a specification sheet from C-F Networks, which included all the necessary data to design other crystal discriminators and tune them.

Excellent 9-MHz crystal filters (manufactured by KVG) are available from Spectrum International.* In addition, monolithic crystal filters and monolithic filter elements are manufactured by Piezo Technology, Inc.† Spectrum International also markets an excellent KVG crystal discriminator for approximately $25.

Quite a few CB crystals are available on the surplus market and in various ham-shack junkboxes so one of these 27 MHz, third-overtone crystals was put into a breadboard circuit and carefully tested at its fundamental frequency, 9 MHz, for modulation acceptance, recovered audio and distortion. Modulation acceptance was sufficient for 5 kHz deviation but more than 7 kHz deviation caused slight audible distortion. A 12 kHz bandpass filter would provide a perfect match for the discriminator.

The crystal used for the tests was a channel-1 transmit crystal for a Heathkit Model CB-1. It is a 26.965 MHz, third-overtone crystal identical to those used in hundreds of other CB radios. This particular crystal is in the larger HC-6/U holder but many are in smaller holders.

The circuit

Fig. 1 is the schematic of the crystal discriminator circuit. Capacitor C3 is adjusted for zero voltage with an unmodulated carrier at center frequency but this setting may not hold for all crystals, and it is possible to obtain good performance and good audio re-

fig. 1. Low cost fm crystal discriminator uses third-overtone channel-1 CB crystal (26.965 MHz) at its 9-MHz fundamental. Response curve of this circuit is plotted in fig. 2.

KVG crystal discriminator for approximately $25.

fig. 2. Response of the 9-MHz crystal discriminator. The linear section of the response curve just above the fundamental resonant frequency is the portion actually used. Good filtering is required ahead of this discriminator or serious audio distortion will result.

The circuit

Fig. 1 is the schematic of the crystal discriminator circuit. Capacitor C3 is adjusted for zero voltage with an unmodulated carrier at center frequency but this setting may not hold for all crystals, and it is possible to obtain good performance and good audio re-

fig. 3. Amplifier/limiter for driving the crystal discriminator uses a Motorola MC1355P integrated circuit.

* Spectrum International, Box 1084, Concord, Massachusetts 01742.
† Piezo Technology Inc., Post Office Box 7877, Orlando, Florida 32804.
covery from crystals that will not tune for a zero center. This just means that the crystal doesn't provide a good linear portion at exactly 9 MHz but with inexpensive, surplus crystals you can't be too particular.

Capacitors C1 and C2 are most easily adjusted with an audio-frequency sine wave applied to an fm signal generator or transmitter and using an oscilloscope to check distortion of the recovered audio sine wave. This same method should be used to align quadrature detectors, too, since there is no true zero-center reading. With a 1 volt p-p i-f signal (at 9 MHz) and 5 kHz deviation, the recovered audio will be about 1 volt p-p at the lower audio frequencies, rolled off at the higher frequencies with the de-emphasis network. The de-emphasis circuit also removes most of the remaining 9 MHz from the audio.

This type of crystal discriminator is amplitude sensitive and requires a good limiter ahead of it to provide a-m rejection. The slope of the discriminator is shown in fig. 2 but may vary a little with different crystals. It is possible to detect fm on the descending portion of the curve about 40 kHz lower but modulation acceptance is only a few kHz.

The Motorola MC1355P is an excellent IC to drive this discriminator. Fig. 3 shows a possible circuit, but the MC1355P has more than 60 dB gain available so it requires very careful layout, bypassing and shielding.

If you're not a reformed CBer it's possible to cultivate a friendship with a CBer who has recently acquired a vfo or you may opt to purchase a new crystal from JAN Crystals* for $2.50.

*JAN Crystals, 2400 Crystal Drive, Fort Myers, Florida 33901.

October 1975
TOUCH TONE ENCODERS

SOLID STATE CRYSTAL CONTROL TONE ENCODERS

- 12 or 16 Touch Tone digits
- Ideal for hand held units
- Choice of 4 keyboard styles
- RF proof
- Temperature, -20° to 150°F
- CMOS IC Encoder
- Bell System Compatibility
- Easy Installation
- Sub-miniature size
- Crystal Controlled
- Single Tone capability
- Low cost

SELF-CONTAINED KEYBOARD ENCODERS

Complete 12 or 16 digit Touch Tone keyboard encoders for mounting directly to side of hand-held transceivers. All electronics included WITHIN keyboard, nothing to add inside of transceiver. Only 1/4" thick. Ready for easy installation, just add three connections to unit. RF proof. Select keyboard style when ordering.

DTM $49.50

SUB-MINIATURE TOUCH TONE ENCODER AND KEYBOARD

Touch-Tone encoder for mounting INSIDE hand-held transceiver, keyboard mounts on side of transceiver. P.C. board only 0.8" x 1.2". RF proofed. Assembled and ready for easy installation. Select keyboard style when ordering.

SME $29.50

DO IT YOURSELF ENCODERS

Now, buy all the major parts — "ala-carte" and build your own Touch Tone Encoder. All you need is a Keyboard, Digital Touch Tone Encoder, a 1-MHz crystal, and P.C. board. Parts come with complete set of application notes, schematics and instructions.

Keyboard, your choice of keyboard style...
Digital T. T. Encoder with 1-MHz HC-6 Crystal...
Digital T. T. Encoder with 1-MHz Slim HC-6 Crystal...
P.C. board 0.8" x 1.2...
All resistors, capacitors, and P.C. board...

(With purchase of keyboard, encoder and crystal)

AUTOMATIC TOUCH TONE DIALER

Automatic mobile telephone dialing is now available. By the push of a single button you can automatically dial up to six separate 7-digit numbers. All solid-state micro-power CMOS design. Automatic PTT operation. Programmable to send telephone number only, access code plus phone number or telephone number plus an identification number. Low profile dash mount, easy installation. Compatible with most radio equipment. Available with keyboard for manual dialing of numbers. Manual operation provides automatic PTT operation with 1½ second transmitter hold.

AD-6 Without keyboard 99.50
AMD-6 With keyboard 119.50

Factory programming of numbers $7.50.

DATA SIGNAL, INC.
Successor to Data Engineering, Inc.
2212 PALMYRA ROAD, ALBANY, GA. 31701
912-435-1764
TOUCH TONE TO DIAL PULSE CONVERTER

Convert standard 0-9 touch tone digits to Bell System compatible dial pulse code. Completely solid state. Includes state-of-the-art Phased Locked Loop anti-falsing touch tone decoder, large capacity 64-digit memory and solid state pulser. Starts dialing on first incoming digit. Memory will not become congested due to rapid succession of incoming digits. Cancel and redial function. *'s and # digits are decoded and provided for remote control purposes. Available as p.c. board or rack mounting.

DPC-121 P.C. Board $195.00
DPC-121R Rack Mount $285.00

ANTI-FALSING TOUCH TONE DECODER

Now, a true anti-falsing decoder/receiver. Virtually immune to high noise or audio falsing. Twelve or 16 digit capability. Completely solid state, uses latest Phased Locked Loop decoding. Single 5-volt power supply. Heavy duty transistor output. Available as p.c. board or 19" rack.

TTD-126-12 12 digit P.C. $149.95 Rack $219.95
TTD-126-16 16 digit P.C. $169.95 Rack $239.95

REPEATER AUTO PATCH

It's complete — a single digit access/disconnect Auto Patch facility. All you need is a repeater and the phone line. Complete with automatic disconnect, dialing capability, two way audio monitor plus remote control. When used with a rotary dial exchange, Data Signal's DPC-121 dial converter is also required. P.C. board or Rack Mount available.

RAP-2 PC $99.50 Rack $149.50

DELUXE P.C. KEYER

In either a 5 volt TTL or a 9 volt C-MOS version this new module type IC keyer can be easily adapted to your own custom package or equipment.

Versatile controls allow wide character weight variation, speeds from 5 to 50 w.p.m. plus volume and tone control.

Solid-state output switching saves power. Eliminates all those annoying relay problems and is compatible with both grid block and solid-state circuitry.

With its side-tone monitor and 90 day warranty the Data Signal PC Keyer is the one for you.

TTL Keyer Wired $19.95
C-MOS Keyer Wired $24.95

DELUXE RECEIVER PREAMP

Specially made for both OLD and NEW receivers. The smallest and most powerful single and dual stage preamps available. Bring in the weakest signal with a Data Preamp.

This New Unit meets the best spec of all: It Low Price! The GTX-1 is NOT a “cheap” import. It IS identical to Genave’s Land Mobile and Aircraft units for high quality and reliability. Compare performance to Motorola, GE, RCA or any other hand-holds that sell for $700 or more . . .

**NEW! from Genave**

**GTX-1 HAND-HELD 2-Meter FM Transceiver**

NOW CHECK THESE FEATURES:
- All Metal Case
- American Made
- Accepts standard plug-in crystals
- Features 10.7 MHz crystal filter
- Trimmer caps on TX and RX crystals
- 2.5 watts output
- Battery holder accepts AA regular, alkaline or nicad cells
- Mini Handheld measures 8” high x 2.625” wide x 1.281” deep
- Rubber ducky antenna, Wrist safety-carrying-strap included
- 6 Channels
- Factory-direct to You

**Accessories Available:**
- Nicad Battery Pack
- Charger for GTX-1 battery pack
- Leather carrying case
- TE III Tone Encoder for auto patch

**GTX-1**
- 2 Meter 6 channel Hand-Held (without encoder)
- $279.95 (Reg. $299.95)

**GTX-1T**
- with Built-In Tone Encoder
- $329.95 (Reg. $349.95)

an extraordinary combination of digitally synthesized receivers...

each with built-in capacity to satisfy a broad spectrum of singular applications.

ITT Mackay Marine 3020A and 3021A Radio Receivers feature solid state construction, dual conversion and super-heterodyne design providing continuous frequency coverage from 15kHz to 29.9999MHz. Frequency selection is accomplished by step tuning, while the 3021A Receiver uses sweep tuning. These receivers meet strict requirements of British MPT, German FTZ, Norwegian NTA, Dutch and Spanish PTT and Canadian DOC, and can be used wherever maximum reliability and ease of maintenance are required.

Write or call Ed Engebretson, General Sales Manager (K4IQD), today for complete information on these two quality, high performance receivers.

ITT Mackay Marine, 2912 Wake Forest Road, Raleigh, North Carolina 27611. Telephone: (919) 828-4441.

Our new priority crystal processing, using a mark sensing order system, is designed to expedite orders for International Crystals and EX Kits. It's another effort to improve our order processing and make a proven reliable system even better. Your order in the future will be processed by using mark sensing order cards and prepunched name and address cards. Complete and return the coupon and we will mail you a special kit containing instructions, order cards and a prepunched name and address card. This is the first step in our new "no delay" order processing.

Element for element, our rugged High-Q beam antennas are designed to give you the biggest signal your transmitter is capable of.

Now when you install one of these Swan antennas you can make sure you’re running full bore all the time by hooking our new SWR/RF Power meter in the coax.

**Heavy duty 4-element Tribander**
Four elements work on 10, 15 and 20 meters. Optimum spacing for maximum performance. Precision tuned, weatherproof traps. 100-mpg winds. TB-4HA. $249.95

**Heavy duty 3-element Tribander**
Three elements work on 10, 15 and 20 meter bands. Rugged construction. Precision tuned, weatherproof traps. Excellent performance on lighter tower. TB-3HA. $189.95

**Economy 2-element Tribander**
Light enough for standard TV rotator but withstands 80 mph winds. Two working elements on 10, 15 and 20 meters. TB-2A. $129.95

**Heavy duty 2-element 40-meter Beam**
Two elements on steel beam. Maximum performance for 40-meter CW or phone. Big, weatherproof high-Q loading coils. Easily takes 100 mph winds. MB-40H. $189.95

**SWR/RF Power meter**
Combination meter measures standing wave ratio and antenna power. Low insertion loss lets you leave it in circuit. 3.5 to 150 MHz. $21.95

80-Meter $3.00 (160-meter not avail.) Crystals for 2-Meter, Marine, Scanners, etc. Send for Catalog.

For 1st class mail, add 20¢ per crystal. For Airmail, add 25¢. Send check or money order. No dealers, please.

**ME-3 microminiature tone encoders**

- Powered by 6-F24C, unregulated
- Micro-miniature in size to fit inside all mobile units
- and most portable units
- Field adjustable, plug-in, frequency determining element
- 6-position frequency accuracy and temperature stability
- Crystal, quartz dual-potentiometer
- Ease of installation; tunable output
- Extremely low in all VSWR, noise frequencies, 67.0 MHz, 20.5 MHz
- Completely isolated to RF
- Internal output protection built-in

**$29.95 each**

More Details? CHECK-OFF Page 110
The HAL DKB-2010 Dual Mode keyboard is one of the most sophisticated products ever offered to the radio amateur. It's an all solid state keyboard that allows you to send either RTTY or CW — with more ease, more versatility than anything you've ever seen before.

In the RTTY mode, you can transmit at standard data rates of 60, 66, 75 or 100 WPM, as well as an optional 132 WPM, 100 baud. In addition to the complete alphanumeric keys, you get 17 punctuation marks, 3 carriage control keys, 2 shift keys, a break key, 2 three-character function keys, a "DE-call letters" key and a "Quick brown fox..." test key.

In the CW mode, you can send at speeds anywhere between 8 WPM and 60 WPM. You can also adjust dot-to-space weight ratios to your liking. For CW, you have all alphanumeric keys, plus 11 punctuation marks, 5 standard double-character keys, 2 shift keys, a break-for-tuning key, error key, "DE-call letters" key, plus 2 three-character function keys. Output interfacing is compatible with cathode keying or grid-block keying. A side tone oscillator and built-in speaker allow you to monitor your signal — with adjustable volume and pitch controls.

The DKB-2010 also has a three-character memory buffer which operates in either the RTTY or CW mode, allowing you to burst type ahead without losing characters. A 64-character memory buffer is also available as an option. Key function logic in either mode is governed by LSI/MOS circuitry. All key switches are computer grade.

The DKB-2010 is available assembled or in kit form. Should you choose the kit, you'll find construction easy — the unit consists of three assemblies: power supply board, logic PC board, keyswitch PC board, and pre-assembled wiring harness.

Any way you look at it — as an easy-to-build kit, a complete assembly, as a CW keyboard, or an RTTY keyboard, the HAL DKB-2010 is a real breakthrough for every amateur. It adds a whole new dimension to the exciting world of amateur radio. Once you've used the DKB-2010, you'll wonder how you ever got along without it!

October 1975 81
We are happy to announce a new addition to our keyboard and encoder line. Our new KBD-3 uses a one chip MOS encoder system to give you maximum possible features with a minimum number of parts.

This keyboard produces a standard ASCII coded output that is compatible with TTL, DTL, RTL and MOS logic systems. You have the option of wiring the kit for normal typewriter style output in both upper and lower case letter, or all upper case format. All common machine control commands such as “line feed”, “return”, “control”, etc. are provided on the keyboard. Four uncommitted or extra keys are available for your specific use requirements. Two of these have isolated output lines to the connector for special functions such as “here is”.

Keyswitches are standard, full travel style with gold plated contacts for long troublefree service. Requires +5 Volts and -12 Volts.

KBD-3 Keyboard and Encoder Kit $49.50 ppd

Vanguard Now Has the World's Largest Selection of Frequency Synthesizers from $129.95

Send No Money. We Ship C.O.D. Order by Phone and Save Time.

Available for Aircraft, Fire, Police and Amateur Frequencies

Check these features:
- Smallest size of any commercially available synthesizer — only 1-3/8" x 3-3/4" x 2".
- Excellent spectral purity since no mixers are used.
- .0005% (5 parts per million) accuracy over the temperature range of —10 to +60 C.
- Immune from supply line voltage fluctuations when operated from 11 to 16 volts D.C.
- Up to 8000 channels available from one unit. Frequency selected with thumbwheel switches.
- Available from 5 MHz to 169.995 MHz with up to 40 MHz tuning range and a choice of 1, 5 or 10 kHz increments (subject to certain restrictions depending on the frequency band selected).
- Top quality components used throughout and all ICs mounted in sockets for easy servicing.
- All synthesizers are supplied with connecting hardware and impedance converters or buffers that plug into your crystal socket.

Vanguard frequency synthesizers are custom programmed to your requirements in 1 day from stock units starting as low as $129.95 for transmit synthesizers and $139.95 for receive synthesizers. Add $20.00 for any synthesizer for 5 kHz steps instead of 10 kHz steps and add $10.00 for any tuning range over 10 MHz. Maximum tuning range available is 40 MHz but cannot be programmed over 159.995 MHz on transmit or 169.995 MHz on receive (except on special orders) unless the i-f is greater than 10.7 MHz and uses low side injection. Tuning range in all cases must be in decades starting with 0 (i.e. — 140.000 — 149.995 etc.). The output frequency can be matched to any crystal formula. Just give us the crystal formula (available from your instruction manual) and we'll do the rest. We may require a deposit for odd-ball formulas. On pick-up orders please call first so we can have your unit ready.

Call 212-468-2720 between 9:00 am and 4:00 pm Monday through Friday

196-23 Jamaica Ave. Hollis, N. Y. 11423

SW-5 — $87.40

The SW-5 is a remote controlled RF switch with indicator lights telling which antenna is in use. It will handle 4 Kw PEP and more. Remote switch is housed in weather tight hinged box. A six wire #18 cable is required to operate the SW-5. Ham M control cable works fine up to 150'. Heavier cable necessary for longer distances. Remote switch operates off 28 VDC built in power supply. No visible effects on SWR. Zero dB insertion loss. Not recommended above 30 MHz. Standard unit is equipped with UHF connectors but BNC, N, HN, C connectors are available at additional charge. Models available are SW3, 4, 5, 6, 7, 8, 9. Also heavy duty 10KW units. Special switching systems are available. Tell us your needs.

Mastercharge & BankAmericard accepted.

An Equal Opportunity Employer M/F
The Transceiver
you'd expect
in 1980

is ready-now!

From the company that revolutionized hf ham radio by giving you the first all-solid-state low and medium power equipment, comes the entirely new TRITON IV, a transceiver that is truly ahead of its time. The fore-runner Triton II gave you such operating and technical features as instant transmitter tune, full break-in, excellent SSB quality, superb receiver performance, pulsed crystal calibrator, built-in SWR indicator, a highly selective CW filter and efficient home, portable and mobile operation from non-aging 12 VDC transistors.

Now — the TRITON IV gives you all of these — and more. A new push-pull final amplifier with the latest gold metalized, zener protected transistors, operating at 200 input watts on all hf bands 3.5 through 29.7 MHz. Plus a new crystal heterodyne VFO for improved short and long term frequency stability and uniform 1 kHz read-out resolution, even on ten meters.

Unsurpassed selectivity is yours with the new eight pole i.f. crystal filter, and improved spurious rejection results from the new IC double balanced mixer.

The benefits of ALC now extend to output powers less than full rating with a front panel threshold control. When driving linear amplifiers that require less than maximum available power from the TRITON, or when propagation conditions permit reliable contacts at reduced power levels, ALC will hold your output to the desired level.

Many small circuit improvements throughout, taken collectively, add more performance and quality pluses — such things as individual temperature compensated integrated circuit voltage regulators for final bias control and VFO supply; And toroid inductances in the ten and fifteen meter low pass filters, LED indicators for offset tuning and ALC threshold, accessory socket for added flexibility, and sequentially keyed mute, AGC and transmitter circuits for even better shaped and clickless CW.

And to top it all off, the highly desirable case geometry has been maintained, but it has a handsome new look. Bold lettering on an etched aluminum front panel and textured black sides and top make the TRITON IV look as sharp as it performs.

There is nothing like a TRITON IV for reliability, features, value and just pure fun. And — best of all — you do not have to wait until 1980 to own one.

TRITON IV $699.00

For more information about the new TRITON, as well as the full line of accessories that will be available soon, see your dealer or write.

ATTENTION HAMS!
Would you like to be able to put your ideas to use instead of just thinking about them? Contract this service to start your ideas to reality. WE CAN DO:
(A) Analyze your circuit with a computer to see how it will work under different conditions before it is constructed.
(B) Design completely from your ideas any piece of equipment you could dream up.
(C) Construct any piece of equipment you desire.
(D) Supply parts to builders of their own equipment.
You will own ALL rights to any design work contracted for and could market your own ideas. Even make money.
I will be pleased to hear from you.

Make Yourself Heard!

To make yourself heard these days on 2 meters it takes POWER. POWER to hit repeaters and POWER to work simplex. Without an amplifier you’re just part of the QRM, but the RF POWER you’re the guy with the BIG SIGNAL! The PRA 10/80 is designed to give you the most economical BIG SIGNAL on 2 meters. Ten watts in and you’ll get a BIG 80 watts out — for just $93.00. Don’t forget our MINI AMP I kit will give hand held units 25 watts of BIG SIGNAL too! It is compatible with any 100 mw to 3.5 watt rig and offers maximum flexibility for a low price — just $54.95. Call our toll free number or see your local dealer and then MAKE YOURSELF HEARD, your contacts will be glad you did.

Many hams say...

The only thing better than the Drake 4-Line is the Drake C-Line

- 1 kHz Dual Concentric Dial Readout
- Receiver and transmitter lock together in transceive operation
- No side controls
- Iridium cadmium-plated chassis
- Compatible with all previous Drake lines

R-4C Receiver

- 8-pole crystal filter combined with passband tuning, SSB filter supplied
- Provision for 15 additional accessory 500 kHz ranges
- Transistorized audio
- Optional high-performance noise blanker
- AVC with 3 selectable time constants
- Optional 8 pole filters available for CW, AM, RTTY

T-4XC Transmitter

- Plug-in relay
- More flexible VOX operation; including separate delay controls for phone and CW
- Crystal control from front panel for amateur, Mars, commercial uses
- Provision for AFSK RTTY operation

For complete details on the C-Line and other Drake equipment, contact:

R. L. DRAKE COMPANY

**Great New Turn On**

Howard Microsystems introduces MOCO II, the newest and most efficient Morse Code translator in the state of the art.

MOCO II ushers in a new generation of Morse Code readers. Its central processing unit is combined with computer programmed firmware totalling more than 8,000 bits of memory, which permit MOCO II to translate standard alphanumeric Morse Code, even punctuation, automatically.

Simply connect MOCO II to the speaker leads and then just turn it on. No knobs, no adjustments. One switch calibration automatically determines and displays sending speed.

MOCO II is not a kit. It's completely assembled and tested, includes integral power supply, parallel ASCII and Baudot outputs for existing display units.

**PRICE: $199.00**

Available as options are a video display, or a teletype driver with 60 ma. loop supplies.

Order from Howard Microsystems, Inc., 6950 France Avenue South, Minneapolis, MN 55435 (612) 925-2474.

**DISPLAY OPTIONS**

A. Baudot Driver/Interface for TTY: ........ $75.00
B. Video Character Display with VHF TV Modulator: .................. $325.00

---

**THE TIGER**

**15% Savings on Gas**

A Capacitive Discharge Ignition system absolutely guaranteed NOT to interfere with your radios & equally guaranteed to improve your auto's operation and gas mileage.

No rewiring necessary. Engine cannot be damaged by improper installation. Either of three models fits any vehicle or stationary engine with 12 volt negative ground, alternator or generator system. Uses standard coil & distributor now on your engine. Dual switch permits motor work or tune-up with any standard test equipment.

Write for free booklet that not only is the BEST description of CDIs, but also explains the need for such a system. Current prices assured til Jan. '76.

This memory card is for the most part a universal unit that can be used in almost any microcomputer from a HOMERREZ to an ALTAIR 8030. It has an array of 2162 x 8 memory compatible with most standard microcomputer systems. We provide everything from the upper low noise vector logic card to fine quality low profile connectors, in the right 2017. We even include timing diagrams and tantalum bypass capacitors.

$69.95 Per Kit

5 VOLT 1 AMP T2 L SUPPLY

This is a standard TEL power supply using the well known LM308K regulator IC to provide a solid 1 AMP of current at 5 volts.
We try to make things simple for you by providing everything you need in one package, including the hardware for only:

$9.95 Per Kit

PLASTIC INSTRUMENT CASE

These cases are fine quality units made by a German manufacturing firm which fit to the dimensions of our DVM and COUNTER kit with room enough left for power supply or batteries. Excellent for many other projects as well. Dimensions 2" x 3.5/8" x 5/8".

$5.95 Per Case

DIGITAL VOLTMETER

This is a 3 1/2 digit, $2.95 vol Digital Voltmeter, with a 0.5% full scale accuracy. It is based around the Siliconix L0119, L0111 DVM chip set. The voltmeter uses MANT7 readouts (.3" high) to provide a highly readable display. The unit requires the following supply voltages, 12, 12, 5. The unit comes complete with all components to build the unit pictured at the left, that is a complete DVM less power supply.

$39.95 Per Kit

DIGITAL COUNTER

This is a 4 digit counter unit which will count up to 9999 and then provide an over flow pulse. It is based around the Monobak 65007 digital counter chip. The unit performs the following functions: Count Input, RESET, Latch, Overflow. The counter operates up to 250 KHz. The counter is an ideal unit to be used as a frequency counter, where the only extra components needed would be a timebase, divider and gate. The unit requires 5V, and +12V. The unit comes complete as shown on the left, less power supply.

$29.95 Per Kit

ONE KILOBYTE RANDOM ACCESS MEMORY

DIPOLE ANTENNA CONNECTOR

HY-E-QUE (HQ-1) dipole connector has coax SU-259 socket molded into glass filled plastic body to accept coax PL-259 plug on feedline. Dip- cap keeps coax fittings dry. Instruc- tions included. Guaranteed. At your dealer's or $3.95 postpaid. Com- panion insulators 2/29.99.

It's here! A rugged, stable 450 MHz solid state amplifier that extends your communications range, while improving performance.

If you thought all 450 amps are the same, look again. Presenting the CPI series of high reliability amateur UHF power amplifiers. They're what's new in amps. They're all solid state, using internally matched RF power devices, and rugged into infinite VSWR at all phase angles.

Available in five versions, including a linear model for single sideband operation, the series offers from 25 to 60 watts of power output.

They're rated for broadband 430 to 450 MHz operation, and they never need tuning. In-line installation is no problem because of automatic internal RF detection and switching.

Best of all, they're compatible with your equipment as it is. They're for mobile units (13.6v DC) only, with FET receiver preamp also available.

No strain on your equipment budget either. Prices start at $119.95.

SUPER LOGARITHMIC SPEECH PROCESSOR
MODEL LSP-520BX

400% MORE RF POWER is yours with this plug-in unit. Simply plug LSP-520BX into the circuit between the microphone and transmitter and your voice suddenly is transformed from a whisper to a DYNAMIC OUTPUT!

Look what happens to the RF Power Output on our NCX-3. It was tuned for normal speech patterns. This unit is practically distortion-free even for RF protection.

LSP-520BX tubing is-putting the RF Power Output once more into the range of 30dB for clean audio response. Adds strength in weak valleys of those frequencies that yield maximum intelligibility. Three active filters concentrate power on three critical frequencies that best support normal speech patterns. This is accomplished through use of an IC logarithmic amplifier with a dynamic range of 30dB for clean audio operation and then left untouched for these "before" and "after" oscillograms.

Three active filters concentrate power on those frequencies that yield maximum intelligibility. Adds strength in weak valleys of normal speech patterns. This is accomplished through use of an IC logarithmic amplifier with a dynamic range of 30dB for clean audio with minimum distortion.

This unit is practically distortion-free even at 30dB compression! The input to the LSP-520BX is completely filtered and shielded for RF protection.

Size is a mere 2 3/16H x 3/4W x 4D. Money back if not delighted and ONE YEAR UNCONDITIONAL GUARANTEE.

Order now or write for FREE brochure.

THE BEST WAY TO MONITOR RADIO CHANNELS WITHOUT LISTENING

TOUCH-TONE® DECODER $75.00

LOWEST PRICE EVER OFFERED FOR A QUALITY TOUCH-TONE DECODER

MAYNARD ELECTRONICS recently purchased the entire stock of discontinued models of PLL TOUCH-TONE DECODERS from a major commercial manufacturer. Our agreement stipulates that the sale of these units will be limited to the amateur radio market. Because the sale price is below the manufacturer’s cost, it is necessary to limit sales to five units per ham to prevent commercial speculation.

FEATURES:
- Virtually immune to falsing by voice, CTCSS tones, music and noise
- Includes a CALL LIGHT and BUZZER
- Output for vehicle HORN connection
- Relay UNMUTES SPEAKER when call is received
- Field programmable for UP TO EIGHT DIGIT code sequences
- May be used for MOBILE or FIXED
- Designed for 12 VOLTS DC Pos. or Neg. operation
- Dimensions: 1½ x 4¾ x 5 15/16 inches

Units are brand new. Complete satisfaction is guaranteed. If for any reason you are not completely satisfied, just return the undamaged unit within ten days for refund.

MODEL 2000B TOUCH-TONE DECODER AND MANUAL $75.00

MATING CABLE. MULTI-CONDUCTOR CABLE WITH MOLEX CONNECTOR $10.00

Please enclose check or money order for the total amount plus $5.00 for shipping and handling. A $10.00 deposit is required on C.O.D. shipments. F.O.B. Belmont.

Include your name, shipping address, zip code and ham call sign. Calif. residents add sales tax.

Journal, articles, news, DX, VHF, classified ads.
Sample 30¢. $3.00 per year. Box 837, Royal Oak,
Michigan 48068.

PC's, Send large S.A.S.E. for list. Semtronics, Rt.
3, Box 1, Bellaire, Ohio 43906.

YOUR AD belongs here too. Commercial ads $35e
per word. Non-commercial ads $10¢ per word.
Commercial advertisers write for special discounts
for standing ads not changed each month.

A Brokerage
for HAM GEAR??

That's right. Now there's a place you can call to find
out who's selling the equipment you're looking for —
absolutely free. Sound incredible? BUYERS & SELLERS
radio brokerage compiles its listings from sellers all
over the country for all kinds of radio gear, test equip-
ment, etc. If you're looking for ham gear, give us a
call. We'll put you in touch with someone selling the
gear you want usually in your vicinity.

If you've got something to sell, or have some equip-
ment that's been collecting dust, let us know about it.
Sellers list their equipment at no charge and pay
a 10% commission of the asking price only if we
find you a buyer and a sale is made.

Do it now! Get together a list of gear you have to
sell and/or would like to buy, give us the details,
and we'll do the rest. When writing be sure to in-
clude your callsign, name, address, telephone, make
and model of unit you're buying or selling. Sellers
should also include the age, condition, price, and all
serial nos.

Put your best fist forward.

To be one of the best fists on the air, all you need is a little practice and the HAL 2550 Keyer and its precision-built companion, the FYO Key.

The 2550 features a triggered clock pulse generator, sidetone monitor, iambic keying and dot memory. There's an optional tailor-made ID too.

Many amateurs remember the famous FYO Key, a key infinitely adjustable to every fist. Now it's back again, better than ever, and available only from HAL. The 2550 Keyer and the FYO Key make a great combination.

So to put your best fist forward, send today for a detailed brochure on these two great products.

110 october 1975
The New Hy-Gain 270 brings state-of-the-art design to 2 meter mobile.

The Hy-Gain 270 is specifically designed to solve the problems of gain 2 meter mobile antennas…hard tuning, high VSWR, poor pattern due to irregular ground plane, and fade from whip flex. The all white fiberglass and chrome design develops 6 db gain through the use of 2 stacked 5/8 wave radiators with a self-contained 1/4 wave decoupling system. Because the Hy-Gain 270 operates independent of the car body ground, you get minimum pattern distortion for maximum range in all directions. Independence from the car body also means the end to tune-up problems. The fiberglass design solves the fading problem due to upper whip flex. Since the antenna and feedpoint are sealed in fiberglass, the Hy-Gain 270 will deliver top performance year after year without loss due to corrosion. The Hy-Gain 270 can be mounted anywhere …bumper, cowl, deck or mast…for fixed, land mobile or marine service using Hy-Gain mounts listed below.

- 6.0 db gain.
- 250 watt rated.
- 144-148 MHz.
- VSWR less than 1.5:1 at resonance, 6 MHz Bandwidth.
- 96’’ whip height.
- No pruning required, completely factory tuned!
- 50 ohm input.
- 3/8 x 24 standard mobile thread.
- Comes with 18’ coax and PL-259 connector.

Order No. 270

Mounts—Universal No. 271
Flush Body No. 499
Bumper No. 415

Get maximum range…get a Hy-Gain 270!

For prices and information, contact your local Hy-Gain distributor or write Hy-Gain.
If you are on 2-meters now
... but you’re tired of being stuck with too few channels
... and you’d like more versatility
... and you really do need tunable VFO
... and SSB-CW (don’t forget OSCAR!)

... you need Kenwood’s NEW

TS-700A

It solves all of these problems and lots more. And best of all... the TS-700A reflects the type of quality that has placed the Kenwood name out front.

- Operates all modes: SSB (upper & lower), FM, AM, and CW
- Completely solid state circuitry provides stable, long lasting, trouble-free operation
- AC and DC capability. Can operate from your car, boat, or as a base station through its built-in power supply
- 4 MHz band coverage (144 to 148 MHz) instead of the usual 2
- Automatically switches transmit frequency

600 KHz for repeater operation... reverser too

- Outstanding frequency stability provided through the use of FET-VFO
- Zero center discriminator meter
- Transmit/Receive capability on 22 channels with 11 crystals
- Complete with microphone and built-in speaker
- The TS-700A has been thoroughly field-tested. Thousands of units are in operation throughout Japan and Europe

The TS-700A is available at select Kenwood dealers throughout the U.S. For the name of your nearest dealer, please write.

Kenwood... pacesetter in amateur radio

More Details? CHECK-OFF Page 110
Henry Radio now offers the Kenwood TS-520 with a built-in frequency display. This equipment is a standard, new TS-520 modified by Henry Radio to include a four digit frequency readout to 100 cycles. If you have never experienced the pleasure of a direct frequency readout, you have a big surprise coming. As fast as you tune the transceiver, the TS-520 displays the actual transmit and receive frequencies. The LED readout is bright and easy to read. There is no chance of confusion, no chance of operating out of the band or on unauthorized frequencies. Your new digital system simply brings a new dimension of pleasure and accuracy to amateur radio.

The TS-520 digital offers a four digit instantaneous display of both the transmitted and received frequencies to a resolution of 100 Hz for easy interpretation by the operator. The operation of the display is interlocked into the standard controls of the transceiver, band switching, sideband switching, and RIT are all automatic. The digital circuits are incorporated directly inside the transceiver and do not affect the normal operating characteristics of the equipment.

Henry Radio will also install the digital modifications into any customer's transceiver if the equipment is returned prepaid to our Los Angeles address.

TS-520 Digital Transceiver $729.00
TS-520 Retrofit Modification $129.00

Enjoy distortion free SSB operation with the advantages of solid state circuitry. Operates in the VHF frequency range of 144-148 MHz with power output of 100W (nom) with 10W (nom) in. Guaranteed to effectively increase both the range and clarity of your communications under all operating conditions.

Modern solid state technology is used throughout, along with conservatively rated components to assure the highest possible reliability. Microstrip design on glass epoxy circuit boards give added resistance to damage from shock or prolonged vibration.

The Tempo 100AL10 is available at Tempo dealers throughout the U.S. Specifications available upon request.

Also available in the fine Tempo line is the famous Tempo ONE, the Tempo 2000, 2002, 2006, 6N2, CL-146A, CL-220, DFD/ONE, DFD/K, FMH, RBF-1, TDC and a broad selection of RF amplifiers.

The "no tune-up" Alpha 374 is powered by EIMAC 8874's.

EIMAC 8874s were the first choice of Ehrhorn Technological Operations, Inc. for their desk-top Alpha 374 bandpass linear amplifier. It's designed to make it easier than ever before to run maximum legal power on all popular modes—it's capable of continuous operation at a kilowatt average power input for CW, RTTY and SSTV—with plenty of reserve for two kilowatts PEP on SSB.

Besides power, the Alpha 374 permits total "no tune-up" operation with modern broadband transceivers. With conventional exciters, it eliminates time, confusion and damage risk previously associated with amplifier tune-up. "Manual" or "Bandpass"—the choice is yours with the 374.

An amplifier like this obviously requires exceptional output tubes. And EIMAC 8874 high-mu, ceramic-metal triodes fill the bill. Three 8874s with axial air-flow cooling fit neatly in a corner of the amplifier—keeping the 374 size down to about one cubic foot and weight below 55 pounds. Yet, the EIMAC 8874s provide 1200 watts plate dissipation, allowing the 374 to coast along at maximum legal power.

For information about the 8874 or other power grid tubes providing the performance, reliability and design flexibility you need, contact EIMAC division of Varian, 301 Industrial Way, San Carlos, CA 94070. Telephone (415) 592-1221.
